Foreword

This Technical Report has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 or greater indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the document.

Introduction

Recently, the GSM network is seeing its greatest expansion due to the increased demand for mobile voice services in emerging markets. Furthermore, most of these emerging markets have densely populated cities and limited radio spectrum. Thus the increase of voice capacity in the circuit switched domain in an evolutionary manner is a key issue for operators in these markets.

To help operators in these scenarios to alleviate the strain on their networks, new techniques are required to improve the voice capacity on the basis of reusing existing network equipment and radio resource. These have been investigated during the MUROS feasibility study and candidate solutions proposed in this feasibility study are based on multiplexing two or more users onto one time slot without degrading the speech quality. These solutions are unlike the speech codec approach to increase network capacity by increasing speech compression, e.g. multiplexing two GSM-HR mobiles onto one time slot but rather to maintain the same speech encoding by multiplexing four GSM-HR mobiles onto one time slot.

The Technical Report is structured in the following way:

Chapter 1 elaborates the scope of the MUROS feasibility study.

Chapter 2 and 3 contain usual elements like References, Definitions, Symobols and Abbreviations.

Chapter 4 lists the defined performance and compatibility objectives for MUROS.

Chapter 5 depicts the common working assumptions for the performance evaluation of MUROS candidate solutions.

Chapter 6 to 9 contain the four candidate solutions for MUROS, in particular:

- the candidate solution 'Speech Capacity Enhancement using DARP' in Chapter 6
- the candidate solution 'Orthogonal Sub Channels for Circuit Switched Voice Capacity Evolution' in Chapter 7
- the candidate solution 'Adaptive symbol constellation' in Chapter 8
- the candidate solution 'Higher Order Modulations for MUROS' in Chapter 9

Chapter 10 lists the proposed candidates for the new set of training sequences.

Chapter 11 depicts aspects related to associated control channel design for MUROS.

Chapter 12 provides a summary of the evaluation versus defined objectives for each of the candidate solutions.

Chapter 13 finally draws conclusions.

1 Scope

The present document is an output of the 3GPP study item 'Multi-User Reusing-One-Slot' (MUROS) [11].

It contains a section describing the objectives of the Circuit Switched Voice Capacity Evolution, and further sections presenting candidate techniques, which are evaluated according to their potential related to voice capacity improvement in GERAN. For this the design of a new set of training sequences with improved cross correlation properties to the existing set of training sequences is foreseen and expected to be evaluated. The study will also include the investigation of different optimised pulse shapes for MUROS for both the uplink and the downlink.

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document *in the same Release as the present document*.

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in TR 21.905 [1] and the following apply. A term defined in the present document takes precedence over the definition of the same term, if any, in TR 21.905 [1].

3.2 Symbols

For the purposes of the present document, the following symbols apply:

α	angle specifying constellation of α-QPSK
A	Offered Traffic
B_ρ	Blocking Probability
C/I	Carrier to Interference Ratio
C/I1	Carrier to First (Strongest) Interferer Ratio
IQ, I-Q	In Phase/Quadrature Phase
χ	cross power ratio between sub channels

3.3 Abbreviations

For the purposes of the present document, the abbreviations given in TR 21.905 [1] and the following apply. An abbreviation defined in the present document takes precedence over the definition of the same abbreviation, if any, in TR 21.905 [1].

ACI	Adjacent Channel Interference
AFS	Adaptive Multi-Rate Full Slot
AHS	Adaptive Multi-Rate Half Slot
AMR	Adaptive Multi-Rate
ARFCN	Absolute Radio Frequency Carrier Number
AWGN	Average White Gaussian Noise
BCCH	Broadcast Control Channel
BER	Bit Error Rate
BSC	Base Station Controller
BSS	Base Station Subsystem
BTS	Base Tranceiver Station
CCI	Co-channel Interference
CIR, C/I	Carrier-to-Interference Ratio
DARP	Downlink Advanced Receiver Performance
DTS	DARP Test Scenario
DTx, DTX	Discontinous Transmission
EFL	Effective Frequency Load
EGPRS	EDGE General Packet Radio Service
FACCH	Fast Associated Control Channel
FER	Frame Erasure Rate
FH	Frequency Hopping
FR	Full Rate
GMSK	Gaussion Minimum Shift Keying
HR	Half Rate
HSN	Hopping Sequence Number
ICI	Inter Channel Interference
IRC	Interference Rejection Combining
ISI	Inter Symbol Interference
JD	Joint Detection
L2S	Link to System mapping
MA	Mobile Allocation
MAIO	Mobile Allocation Index Offset
MAIOA	MAIO Allocation

MAIOHSN	MAIO Hopping Sequence Number
MAIOPN	MAIO Permutation Number
MIMO	Multiple Input Multiple Output
MRC	Maximal Ratio Combining
MSRD	Mobile Station Receive Diversity
MTS	MUROS Test Scenario
MUROS	Multi-User Reusing One Slot
PA	Power Amplifier
PAR	Peak to Average Ratio
PC	Power Control
PSK	Phase Shift Keying
QAM	Quadrature Amplitude Modulation
QPSK	Quarternary Phase Shift Keying
RMS	Root Mean Square
RR	Radio Resource
RRC	Root Raised Cosine
SACCH	Slow Associated Control Channel
SAIC	Single Antenna Interference Cancellation
SCPIR	Sub Channel Power Imbalance Ratio
SIC	Successive Interference Cancellation
SNR	Signal–to-Noise Ratio
TCH/EFS	Traffic channel employing enhanced full rate GSM speech codec
TCH/FS	Traffic channel employing full rate GSM speech codec
TCH/HS	Traffic channel employing half rate GSM speech codec
TCH/AFS	Traffic channel employing AMR full rate codec
TCH/AHS	Traffic channel employing AMR half rate codec
TCH/WFS	Traffic channel employing Wideband AMR full rate codec based on GMSK
TRX	Transceiver
TSC	Training Sequence Code
VAD	Voice Activity Detection

4 Objectives

The increase in user amount and voice traffic puts a huge pressure on operators especially within populous countries. Furthermore, as voice service price gets cheaper, most operators face the challenge to obtain efficient utilization of hardware and spectrum resource. The following performance and compatibility objectives are therefore defined for each MUROS candidate technique.

4.1 Performance Objectives

Two performance objectives are defined.

4.1.1 Capacity Improvements at the BTS

Objective P1: The candidate techniques proposed under MUROS is expected to increase voice capacity of GERAN in order of a factor of two per BTS transceiver. The channels under interest for doubled voice capacity are both full rate and half rate channels: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS with related associated signaling channels.

4.1.2 Capacity Improvements at the Air Interface

Objective P2: The objective is to further enhance the voice capacity of GERAN by means of multiplexing at least two users simultaneously on the same radio resource both in downlink and in uplink. The channels under interest for doubled voice capacity are both full rate and half rate channels: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS with related associated signaling channels.

The co-channel and adjacent channel interference increase with number of users, which leads to the decrease of C/I and frequency reuse. The balance between low frequency reuse and high timeslot reuse should be considered carefully.

4.2 Compatibility Objectives

Five compatibility objectives are defined.

4.2.1 Maintainance of Voice Quality

Objective C1: The introduction of the candidate techniques proposed under MUROS should not decrease voice quality as perceived by the user. In particular a voice quality better than for GSM HR should be ensured. This is due to the fact that in case of sub-channels, being allocated in the same time slot within the same radio frequency, the influence of the inevitable inter-channel interference (ICI) on voice quality and actual proportion of the subscribers sharing the same time slot cannot be ignored.

4.2.2 Support of Legacy Mobile Stations

Objective C2: Support of legacy MS by candidate techniques proposed under MUROS identifies a further MS related objective. No implementation impacts shall be required for legacy MS types. First priority has the support of legacy DARP phase 1 capable terminals, whilst second priority is given the support of legacy GMSK terminals notsupporting DARP phase 1 capability.

4.2.3 Implementation Impacts to new Mobile Stations

Objective C3: The introduction of the candidate techniques proposed under MUROS should change MS hardware as little as possible. Additional complexity in terms of processing power and memory should be kept to a minimum for a new MS.

4.2.4 Implementation Impacts to BSS

Objective C4: The introduction of the candidate techniques proposed under MUROS should change BSS hardware as little as possible and HW upgrades to the BSS should be avoided.

Any TRX hardware capable of multiplexing more than one user on a single ARFCN time slot shall support legacy GMSK mobiles, this includes non-SAIC mobiles and SAIC mobiles.

Impacts to dimensioning of resources on Abis interface shall be minimised.

4.2.5 Impacts to Network Planning

Objective C5: The impacts to network planning and frequency reuse shall be minimised. Impacts to legacy MS interfered on downlink by the MUROS candidate technique should beavoided in case of usage of a wider transmit pulse shape on downlink. Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator''s band allocation and in country border regions where no frequency coordination are in place.

5 Common Working Assumptions for Candidates Evaluation

This section lists the common working assumptions for the performance evaluation of MUROS candidate techniques that were discussed and agreed at GERAN#37 and are reflected in summary report [2].

5.1 General parameters

In this subsection general parameters for the evaluation of MUROS candidate techniques are listed.

Table 5-1: General agreed evaluation parameters

Aspect	Working Assumption
Definition of legacy MS type	- First Priority: evaluation of DARP phase I MS. - Second Priority: evaluation of legacy MS without DARP phase I capability.
Definition of new MS type	Single antenna mobiles. No consideration of DARP phase II mobiles.
Penetration level of certain MS types	Share of legacy MS: $S_{NON-MUROS}$ Legacy MS include both: - legacy MS without DARP phase I (share $S_{NON-DARP}$) - legacy MS with DARP phase I (share S_{DARP}) - constant ratio assumed for S_{DARP} / $S_{NON-DARP}$ = 30 % / 70 % - total share of legacy MS: $S_{NON-MUROS} = S_{DARP} + S_{NON_DARP}$; Share of new MUROS mobiles: S_{MUROS} with S_{MUROS} = 0%, 25%, 50%, 75%, 100% and $S_{MUROS} + S_{NON-MUROS}$ = 100%. [1]
Propagation Environment	Typical Urban.
Training Sequences Optimisation	- Usage of legacy TSC''s only to allow early adoption of MUROS - Usage of combination of existing and new TSC''s with improved cross correlation properties - Usage of new TSC''s with improved cross correlation properties only
Interference cancellation methods	Specific interference cancellation methods are to be studied for DL and for UL.
Transmit Pulse Shapes	First Priority: legacy linearized GMSK pulse shape Second Priority: optimised pulse shape up to 270 kHz BW.
Mobility	Both 3 km/h and 50 km/h
Speech codecs	GSM HR, AFS 12.2, AFS 5.9 and AHS 5.9

[1] For example for a share of new MUROS mobiles of 50 % remaining 50 % are legacy MS. Hence a share of 35 % is assumed for legacy MS without DARP phase I and 15 % for MS supporting DARP phase I.

AMR codec mode adaptation	Not required for MUROS study. Left optional to companies to provide results including AMR codec mode adaptation.
Frequency Hopping	Activated. Case no FH is FFS.
Voice Call Model	Voice calls are generated in the system simulator based on Poisson call arrivals and exponential call durations. The call arrival rate is set according to the load that is to be simulated in the network. The mean call duration is assumed to be 90 seconds, with a minimum call duration of 5 seconds.
DTX	The channel activity time in DTX on DL and on UL, comprising active voice periods and all types of GSM specific signalling blocks is modelled as follows: ▪ activity factor of 60 % with independent channel activity on DL and UL. ▪ mean channel activity time is 1826 ms. Note, the channel activity duration is exponentially distributed. **2** ▪ minimum channel activity time is 60 ms. **3** ▪ minimum channel inactivity time is 185 ms. **4** Note, the channel inactivity duration is also exponentially distributed. ▪ both the actual channel activity time and channel inactivity time shall be rounded to next lower or next higher multiple of 20 ms than the selected value from the distribution to enable sending of complete speech blocks. By this rounding the channel activity should be maintained close to the activity factor.
HW configuration per cell	4 TRX/cell and 6 TRX/cell
BCCH resource utilization	For MUROS-1 and MUROS-2 network configurations, the resource utilization on BCCH carrier is specified as follows: - Timeslots for voice: 3 - Timeslots for data: 4 According to [4], data channels are modelled by the simplified modelling assumption of the presence of GMSK dummy bursts in these time slots.
Network Synchronisation Mode	First Priority: synchronous networks. Second Priority: asynchronous networks All network configurations (see subclause 5.3) will be first evaluated in synchronous mode. Network configuration MUROS-2 will also be evaluated in asynchronous mode. In case of major performance impact due to network synchronization mode at link level, all network configurations need to be evaluated in asynchronous network mode.
Multiplexing of Mobiles	Optimum multiplexing of mobiles on the same physical resource will be studied for downlink and for uplink.

2 Assuming a mean talkspurt duration of 1197 ms and mean silence duration of 1846 ms as defined by the Brady model [3], the total mean periodicity as the sum of mean talkspurt duration and mean silence duration is 3043 ms. Hence the activity factor of 60% yields the mean channel activity time of 1826 ms, which includes GSM specific signalling blocks (SID FIRST, ONSET, SID_UPDATE, NO_DATA).

3 The duration of 60 ms cooresponds to a minimum talkspurt duration including SID FIRST and ONSET blocks (40 ms from VAD model + 20 ms signalling).

4 This corresponds to minimum silence duration of 205 ms from VAD model reduced by 20 ms signalling blocks due to SID FIRST and ONSET.

Power Control	Both DL and UL PC will be enabled (vendor specific). PC management needs to be performed jointly for all sub channels.
Evaluation Output	- Maximum network capacity gain as defined in 3.4 - FER statistics - SNR statistics - Information on call drop rate (if available)

5.2 Definition of Model for External Interferers for Link Level Evaluations

In this subsection the interferer models specifying the profiles related to **external interferers** are described. External interferers are generated outside the serving cell.

Note, absolute performance characterization is given preference for the comparison to legacy TCH channel type for link performance evaluation.

As in [5] the link performance shall be evaluated for FER := 1%. Other FER ratios may also be considered.

5.2.1 Synchronous Network Mode

The link performance per each MUROS candidate technique shall be specified for the following synchronous interferer scenarios:

a) for a new MTS-1 (MUROS test) scenario with synchronous interferer.

Table 5-2: MUROS Test Scenario 1 (MTS-1) with single synchrnous interferer

Reference Test Scenario	Interfering Signal	Interferer relative power level	TSC	Interferer Delay range
1) MTS-1	1) Co-channel 1	1) 0 dB	1) None	1) no delay

Whereby the modulation for co-channel 1 will be either: GMSK or MUROS type.

It should be noted, that at MUROS telco#3 the working assumption was agreed to remove single 8-PSK interferer profile since the results by different vendors did not show a major difference in performance compared to the case of a MUROS type interferer. The same applies for scenarios under b) , c) and d).

Interference performance shall be based on C/I for single external cochannel inteferer, where C is related to the received power accumulated from all subchannels in the serving cell and I to the received power of the single external cochannel interferer.

b) for a new MTS-2 (MUROS test) scenario with multiple synchronous interferers.

Table 5-3: MUROS Test Scenario 2 (MTS-2) with multiple synchronous interferers.

Reference Test Scenario	Interfering Signal	Interferer relative power level	TSC	Interferer Delay range
1) MTS-2	1) Co-channel 1 2) Co-	1) 0 dB 2) -10 dB	1) none 2) none	1) no delay 2) no delay

	channel 2 3) Adjacent 1 4) AWGN	3) 3 dB 4) -17 dB	3) none 4) -	3) no delay 4) -

Whereby the modulation for co-channel 1 will be either: GMSK or MUROS type. The modulation for co-channel 2 will be either: GMSK or MUROS type. The modulation for adjacent 1 will be either: GMSK or MUROS. Only configurations, where all interferers are using the same modulation type, are considered.

Interference performance shall be based on C/I1 for multiple external cochannel inteferers, where C is related to the received power accumulated from all subchannels in the serving cell and I1 to the received power of the dominant external cochannel interferer.

5.2.2 Asynchronous Network Mode

The link performance per each MUROS candidate technique shall be specified for the following asynchronous interferer scenarios:

a) for a new MTS-3 (MUROS test) scenario with asynchronous interferer.

Table 5-4: MUROS Test Scenario 3 (MTS-3) with single asynchrnous interferer.

Reference Test Scenario	Interfering Signal	Interferer relative power level	TSC	Interferer Delay
1) MTS-3	1) Co-channel 1	1) 0 dB *)	1) None	1) 74 symbols

*) The power of the delayed interferer burst, averaged over the active part of the wanted signal burst. The power of the delayed interferer burst, averaged over the active part of the delayed interferer burst is 3 dB higher.

Whereby the modulation for co-channel 1 will be either: GMSK or MUROS type.

Interference performance shall be based on C/I for single external cochannel inteferer, where C is related to the received power accumulated from all subchannels in the serving cell and I to the received power of the single external cochannel interferer.

b) for a new MTS-4 (MUROS test) scenario with multiple asynchronous interferers.

Table 5-5: MUROS Test Scenario 4 (MTS-4) with multiple asynchronous interferers

Reference Test Scenario	Interfering Signal	Interferer relative power level	TSC	Interferer Delay
MTS-4	Co-channel 1 Co-channel 2 Adjacent 1 AWGN	0 dB *) -10 dB 3 dB -17 dB	none none none -	74 symbols no delay no delay -

*) The power of the delayed interferer burst, averaged over the active part of the wanted signal burst. The power of the delayed interferer burst, averaged over the active part of the delayed interferer burst is 3 dB higher.

Whereby the modulation for co-channel 1 will be either: GMSK or MUROS type .

The modulation for co-channel 2 will be either: GMSK or MUROS type. The modulation for adjacent 1 will be either: GMSK or MUROS. Only configurations, where all interferers are using the same modulation type, are considered.

Interference performance shall be based on C/I1 for multiple external cochannel inteferers, where C is related to the received power accumulated from all subchannels in the serving cell and I1 to the received power of the dominant external cochannel interferer.

5.2.2.1 Interferer delay profiles

Interferer delay profiles for asynchronous network operation are foreseen to be specified to model the asynchronous network operation merely on link level in order to generate a specific link to system mapping table used by the network simulator running in synchronous mode. This is aligned to the proceeding in the SAIC Feasibility Study [5] as agreed at GERAN#38. The specification of these interferer delay profiles is FFS.

A propsosal on interferer delay profiles has been submitted to the GERAN 1 Adhoc Meeting on MUROS on 8th/9th April in AHG1-080049. The discussion on these interferer delay profiles is ongoing.

5.2.3 Sensitivity limited scenarios

The link performance per each MUROS candidate shall be specified for sensitivity with AWGN included both in DL and in UL. As agreed at GERAN#38 [6] the SNR is used both for downlink and uplink for sensitivity performance. Power backoff resulting from modulation specific peak to average ratio should be taken into account and be included in the performance results. In order to allow for a direct comparison with the reference case performance results should be calibrated in such way that the power of all subchannels will be accumulated and this total power then is used to define the SNR, both for DL and for UL.

5.2.4 Frequency Offsets

In addition a distribution function for frequency offsets shall be taken into account for each external interferer on DL. It shall be applied in alignment to [5] as follows:

Normal distribution with N(50 Hz,17 Hz) for low band (850/900 MHz).

Normal distribution with N(100 Hz,33 Hz) for high band (1800/1900 MHz).

5.2.5 Uplink Interferer Profiles

In uplink the same profiles MTS-1 through MTS-4 for external interferers are used. In addition the subchannels need to be modelled as described below:

The link level analysis shall be performed for discrete values of the subchannel power imbalance ratios:

SCPIR = -15 dB, -10 dB, -5 dB, 0 dB, 5 dB, 10 dB, 15 dB.

Note at least the performance for the worst subchannel is to be shown.

In addition distributions shall be taken into account for the timing alignment error of both subchannel transmissions and the frequency offset of paired subchannel and of external interferers:

Timing alignment error: a distribution function based on 0.0, 0.5 and 1.0 symbol is used as follows:

a) Probability (0 symbols) = 50%.

b) Probability (0.5 symbols) = 25%.

c) Probability (1 symbol) = 25%.

Note for b) and c) in half of the cases the interferer on the paired subchannel is advanced, and in half of the cases it is postponed related to the signal in the wanted subchannel. Timing alignment error is selected on a burst basis, i.e. independent between successive bursts.

Frequency offset for the paired subchannel and for each external uplink interferer:

A distribution function for the frequency offset shall be taken into account since the MS frequency accuracy is ±0.1 ppm on UL as follows:

a) Normal distribution with N(45 Hz,10 Hz) for low band (850/900 MHz).

b) Normal distribution with N(90 Hz,17 Hz) for high band (1800 MHz).

c) Normal distribution with N(95 Hz,17 Hz) for high band (1900 MHz).

Note, the CIR on uplink is defined as a relative figure for the wanted sub channel under consideration as proposed in [7] and agreed at 3GPP GERAN#39.

5.3 Network Configurations

Both blocking limited and interference limited scenarios are being evaluated to assess the performance of each MUROS candidate technique on system level. Three network configurations named MUROS-1, MUROS-2 and MUROS-3 are depicted in Table 5-6. Additional parameters for system performance evaluation are contained in Table 5-7.

Table 5-6: Selected Network Configurations for MUROS (revised after MUROS telco#1).

Parameter	MUROS-1	MUROS-2	MUROS-3
Frequency band (MHz)	900	900	1800
Cell radius	500 m	500 m	500 m
Bandwidth	4.4 MHz	11.6 MHz	2.6 MHz
Guard band	0.2 MHz	0.2 MHz	0.2 MHz
# channels excluding guard band	21	57	12
# TRX	4	6	4
BCCH frequency re-use	4/12	4/12	N.A.
TCH frequency re-use	1/1	3/9 (***)	1/3 ; 1/1 (**)
Frequency Hopping	Synthesized	Baseband	Synthesized
Length of MA (# FH frequencies)	9	5 (BCCH non-hopping)	4 ; 12 (**)
Fast fading type	Flat / TU	TU	TU
BCCH or TCH under interest	Both	Both	TCH
Network sync mode	sync (async*)	sync / async	sync (async*)

(*): depending on MUROS-2.
(**): reuse 1/1 with 12 frequencies requested by Vodafone post telco#1.
(***): Alternative TCH reuse 3/5.625 with Synthesized FH, MA length 8 and BCCH inclusion requested by China Mobile post telco#1 was removed at GERAN#38 [6].

Table 5-7: Parameters for Evaluation of MUROS system performance.

Parameter	Value	Unit
Sector Antenna Pattern	1) UMTS 30.03, 90° H-plane, max transmitter gain: 13 dBi and 2) 65° H-plane, max transmitter gain: 18 dBi agreed at 3GPP GERAN#39	-
Propagation Model	UMTS 30.03, vehicular path loss model	-
Log-Normal Fading: Standard Deviation	8	dB
Log-Normal Fading: Correlation Distance	110	m
Log-Normal Fading: Inter-Site Correlation	50	%
Handover Margin	3	dB

5.4 Channel Mode Adaptation

Channel mode adaptation is often used in real networks, e.g. when channel conditions become worse at the cell boundary and switching to full rate mode becomes necessary. It makes use of an intracell handover, which may in case of MUROS be initiated more often due to bad signal quality than due to insufficient signal power, and is based on the specified speech codecs in Table 5-1. According to [4] a sophisticated channel mode adaptation comprising switching

between full rate and half rate channels is not required for the purpose of comparing candidate techniques. Instead the following approach has been agreed:

a) For comparison of the candidate techniques a non-MUROS / MUROS adaptation as depicted in Table 5-8 below is applied:

Table 5-8: Channel Mode Adaptation for comparison of candidate techniques

Channel Mode Adaptation	Channel modes
Type A0	GSM HR (Reference case)
Type A1	GSM HR <-> MUROS (GSM HR)
Type B0	AFS 12.2 (Reference case)
Type B1	AFS 12.2 <-> MUROS (AFS 12.2)
Type C0	AFS 5.9 (Reference case)
Type C1	AFS 5.9 <-> MUROS (AFS 5.9)
Type D0	AHS 5.9 (Reference case)
Type D1	AHS 5.9 <-> MUROS (AHS 5.9)

b) For the complete candidate technique to be standardised, a channel rate change between full rate, half rate and MUROS channel type and vice versa as depicted in Table 5-9 needs to be evaluated:

Table 5-9: Channel Mode Adaptation for specification of the candidate technique

Channel Mode Adaptation	Channel modes
Type E0	AFS 12.2 <-> GSM HR (Reference case)
Type E1	AFS 12.2 <-> GSM HR <-> MUROS (GSM HR)
Type E2	AFS 12.2 <-> MUROS (AMR 12.2) <-> MUROS (GSM HR)
Type F0	AFS 5.9 <-> AHS 5.9 (Reference case)
Type F1	AFS 5.9 <-> AHS 5.9 <-> MUROS (AHS 5.9)
Type F2	AFS 5.9 <-> MUROS (AFS 5.9) <-> MUROS (AHS 5.9)

The impact on speech FER due to the usage of channel mode adaptation is required to be taken into account in a vendor specific way.

5.5 System Performance Evaluation Method

The following proceeding was agreed to assess the maximum network capacity gain:

- Step 1: The system is loaded without usage of MUROS candidate technique until minimum call quality performance is not anymore ensured.
- Step 2: The system is loaded with usage of MUROS candidate technique until minimum call quality performance is not anymore ensured.
- Step 3: The performance in terms of network capacity is compared against each other according to the definition:

$$\textit{Network Capacity Gain} = \frac{Capacity(with_MUROS)}{Capacity(without_MUROS)}.$$

Two system performance capacity metrics listed in Table 5-10 are defined. These will be used for BCCH layer, for TCH layer and for total capacity.

Table 5-10: Capacity metrics for MUROS evaluation

Capacity metric	Unit
Spectral efficiency	Erl / MHz / Site
HW Efficiency	Erl / TRX

Note, results should be given in terms of gains relative to the reference case using legacy channel types only, as specified above in Table 5-8 and 5-9.

5.5.1 Definition of Effective Frequency Load for Mixed Frequency Reuse

The following definition is provided to clarify calibration of system performance in terms of EFL in case of a mixed frequency reuse. This refers to the case that both hard blocking and soft blocking performance of MUROS are provided as function of EFL. A unique definition of EFL should be used throughout the vendors for performance comparison. This is needed in particular for network configurations like MUROS-1 and MUROS-2 including TCH channels for MUROS on BCCH and hence employing a mixed frequency reuse based on TCH layer and BCCH layer. This section proposes a unique definition for EFL in case of mixed frequency reuse, given in the equation below.

$$EFL = \frac{A}{N_{Freq} * av(N_{TS_per_TRX})} * 100\% \quad ,$$

with A being the supported traffic in Erl as determined by the simulation (the equation is valid for FR and HR channel modes, taking into account either full rate or half rate channel capacity as the number of supported simultaneous connections for HR channel modes A and D is supposed to be higher than for FR channel modes B and C in most cases), N_{Freq} the number of total frequencies composed of the TCH layer and the BCCH layer and $av(N_{TS_per_TRX})$ the average number of available full rate channels or time slots per TRX derived from the total available timeslots for MUROS usage in both layers and the total number of TRX.

An examplary determination of EFL is given hereafter.

Let us assume the network configuration MUROS-1 with 1 BCCH carrier and 3 TCH carriers. In this configuration the TCH layer uses a frequency reuse 1/1 with 9 frequencies equivalent to the length of the Mobile Allocation, whilst the BCCH layer utilizes 12 frequencies based on frequency reuse 4/12. Further assume both cases.

a) legacy full rate channel mode (e.g. C0) and

b) MUROS full rate channel mode (e.g. C1).

For both cases the average number of timeslots per TRX is given by

$$av(N_{TS_per_TRX}) = \frac{N_{total_TS}}{N_{total_TRX}} = \frac{3*8+3}{3+1} = \frac{27}{4} = 6.75$$

and the total number of frequencies is N_{Freq}=12+9=21.

This yields for both cases

$$EFL = \frac{A}{21*6.75} * 100\% = 0.7055\% * A \ ,$$

with A_a being the simulated supported number of simultaneous connections for case a) and A_b the corresponent one for case b) for evaluation against the hard blocking limit of 2% or against the soft blocking limit (average FER for MUROS FR ≤ 2%, for MUROS HR ≤ 3%).

Note: Evaluation of EFL performance is optional in MUROS feasibility study.

5.6 Definition of Minimum Call Quality Performance

The following criteria for definition of minimum call quality performance were agreed:

- 1st Criterion: blocked calls < 2 %
- 2nd Criterion: satisfied user criterion fulfilled.
    - average call FER < 2 % for at least 95% users in case of FR channel type i.e. for channel mode adaptation types Bx and Cx in Table 5-8.
    - average call FER < 3 % for at least 95% users in case of HR channel type, i.e. for channel mode adaptation types Ax and Dx in Table 5-8.
- 3rd Criterion: the relative performance of associated signalling channels compared against the traffic channel as derived in link performance evaluation for a reference scenario shall be maintained for MUROS channel types.
    - The reference scenario is defined as follows: DTS-2, DARP receiver, definition of mean performance offset of FACCH and SACCH channels.
        - applying corresponding fullrate codec type in case of MUROS fullrate codec.
        - applying cooresponding halfrate codec type in case of MUROS halfrate codec.

Note that the criterion on dropped calls has not been included, as the study is targeting on voice quality under the restiction of sufficient performance of associated siganlling channels. Nevertheless it is left open to the proponents of a candidate technique to add information on call dropped call rate. Note the average call FER threshold has been relaxed from 1% to the above values according to [6] at GERAN#38.

5.7 Link-to-System Mapping

An agreement has been achieved at 3GPP GERAN#39 not to investigate further for DL and for UL the approach of a common Link to System Mapping approach based on some proposals such as provided in [8] and [9].

Instead verification of L2S mapping in the MTS-1 to MTS 4 scenarios shall be performed by each vendor.

- The SCPIR envisaged for the operation of the candidate technique shall be taken into account.
- The evaluation shall be based on uncoded BER only.

The link to system mapping should be verified by the vendor through link level simulations. All modulations used in the system simulations should be verified.

5.8 Impairments of the Mobile Station

5.8.1 Subchannel power imbalance ratio on DL

Discussion at 3GPP GERAN#39 was based on contributions from different vendors reporting performance degradation for legacy SAIC mobiles beyond a certain sub channel power imbalance ratio. The reported range was about 8 to 10 dB.

Since performance was believed to be different for all mobile receivers, vendors believed that it was difficult to agree on a specific value for the maximum power imbalance. Taking this account in system simulations was felt to be complicated as call quality is used as criterion for handovers and not the power imbalance.

Mobile vendors were invited to report any limitations on the SCPIR at the next MUROS telco#6. At MUROS telco#6 it was agreed to not specify a general constraint on limitations related to acceptable subchannel power imbalance ratios on terminal side and to take into account terminal performance in a vendor specific manner.

5.8.2 Frequency Offset Impairment Model in UL

A proposal in [10] to define a lower figure than the current frequency offset of 100 Hz was discussed based on the statement that 40 Hz would be a more realistic assumption for the average frequency offset of each of both mobiles in uplink subchannels. Mobile vendors were invited to report more realistic figures for the expected frequency offset at the next MUROS telco#6. At MUROS telco#6 a refined frequency offset impairment model on UL was agreed. This is depicted in section 5.2.5.

5.9 Reference BTS Receiver

Discussion on introducing a reference BTS receiver type such as dual antenna MRC or IRC during the MUROS feasibility study took place at 3GPP GERAN#39.

Different network vendors preferred the usage of different BTS receiver types. It is agreed that a statement regarding the complexity of the evaluated BTS receiver type for each vendor is included in the Technical Report. It was considered as a limitation to the fesibility study to focus on a single BTS receiver types, as some receiver types may serve one candidate technique better than others. It was also agreed to identify the MUROS performance benefit related to the reference based on the same BTS receiver type.

6 Speech Capacity Enhancement using DARP

6.1 Concept Description

6.1.1 Principle

DARP was specified to provide improved reception on the mobile station side when there is ACI or CCI. However, with good downlink signal quality there is little benefit from DARP. This concept uses this fact to enhance speech capacity.

DARP can work quite successfully with CCI of 0dB. Therefore the network can assign the same physical resources to two mobile stations but allocating them different training sequence codes as depicted in Figure 6-1. Each mobile will receive its own signal (shown in black in the figure) and that intended for the other co-TCH user (shown in red in the figure).

On the downlink, each mobile station will consider the signal intended for the other mobile station as a CCI. The receiving mobile station does not need to support any other enhancements than DARP. For optimum DARP performance, the two signals intended for the two different mobile stations should ideally be phase shifted by $\pi/2$ for their channel impulse response but less than this will also provide adequate performance.

On the uplink each mobile station would use a different training sequence code. The network may use techniques such as joint detection to separate the two users on the uplink.

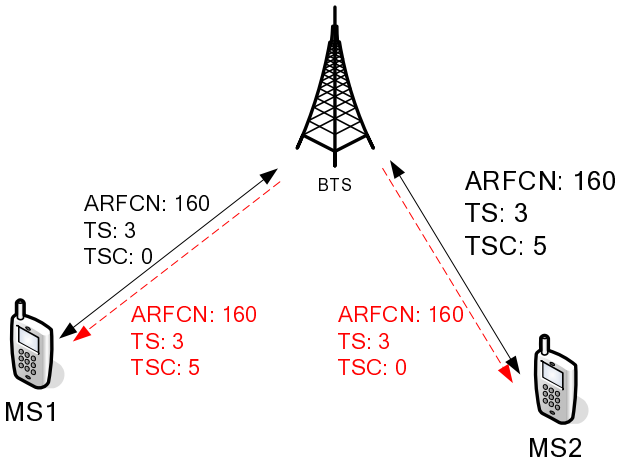

Figure 6-1 Channel assignment for co-TCH operation

The above scheme is applicable to OSC signals (QPSK or alpha-QPSK) MUROS signals. This is referred to in chapter 7 for OSC and in chapter 8 for alpha-QPSK.

6.1.2 Downlink signal modulation schemes

DARP based co-TCH proposal is based on combining two base-band signals [6-1], although RF combining also works for feasibility demo [6-2].

For future MUROS deployment one way of generating the DL signal is to linearly combine the two GMSK baseband modulated signals and then feed into the RF modulator and power amplifier for transmission as shown in Figure 6-2.

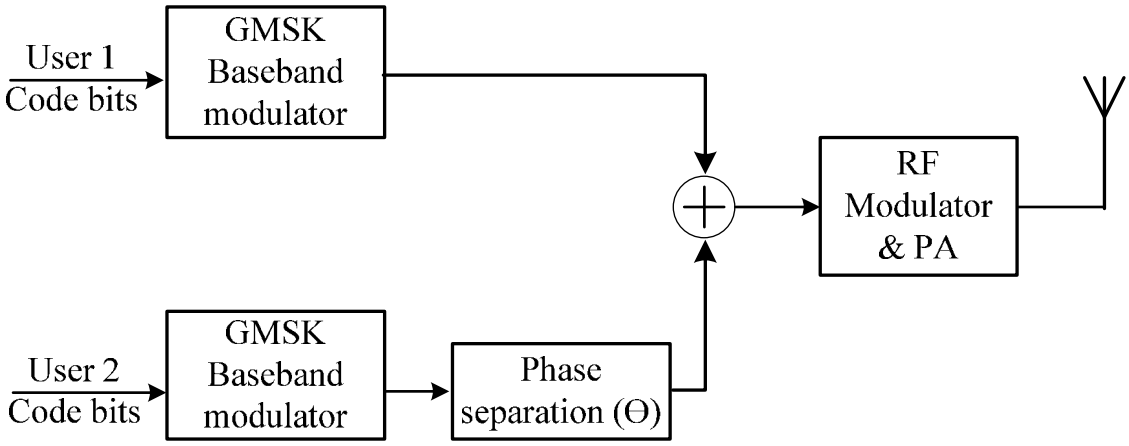

Figure 6-2 Linear baseband combining for co-TCH

The DARP based co-TCH MUROS method also works with QPSK as well as GMSK modulation schemes.

In this section a case analysis of three different types of MUROS modulation schemes for DL signals and their spectrums is presented. They are

1. Linear sum of two GMSK signals (90 degree phase separation),

2. QPSK with liner Gaussian filter, and

3. QPSK with RRC (roll off 0.3) filter.

6.1.2.1 Equal power level between two desired users

When two DARP phones with similar path loss are paired as MUROS callers, the power level provided to them should be the same.

The I-Q plots for the three modulations schemes are shown in Figure 6-3.

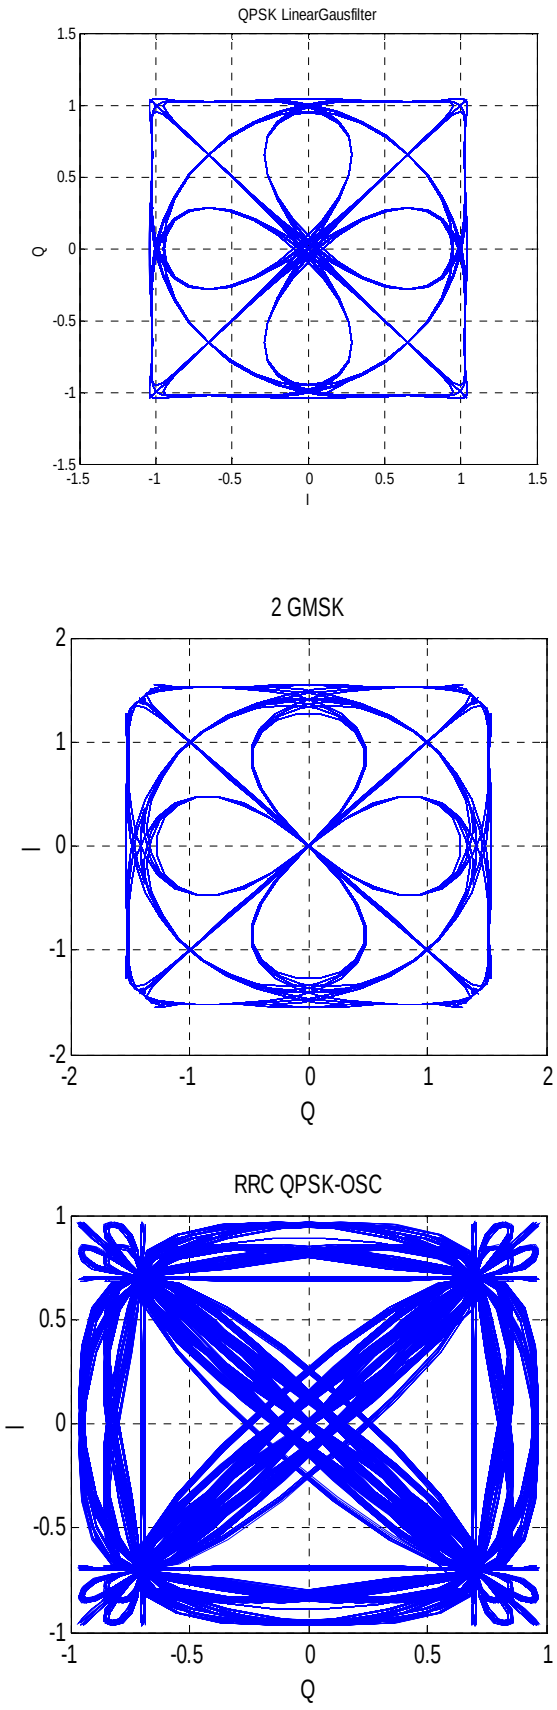

Figure 6-3 Baseband IQ plots for three MUROS DL modulation schemes

It can be seen that two GMSK linear combination and QPSK with Linear Gaussian filter have very similar I-Q plots.

6.1.2.2 Spectrum analysis

The spectrum analysis of the above three MUROS DL schemes are shown in Figure 6-4. Some difference is observed when compared with reference [6-3] and need further clarification.

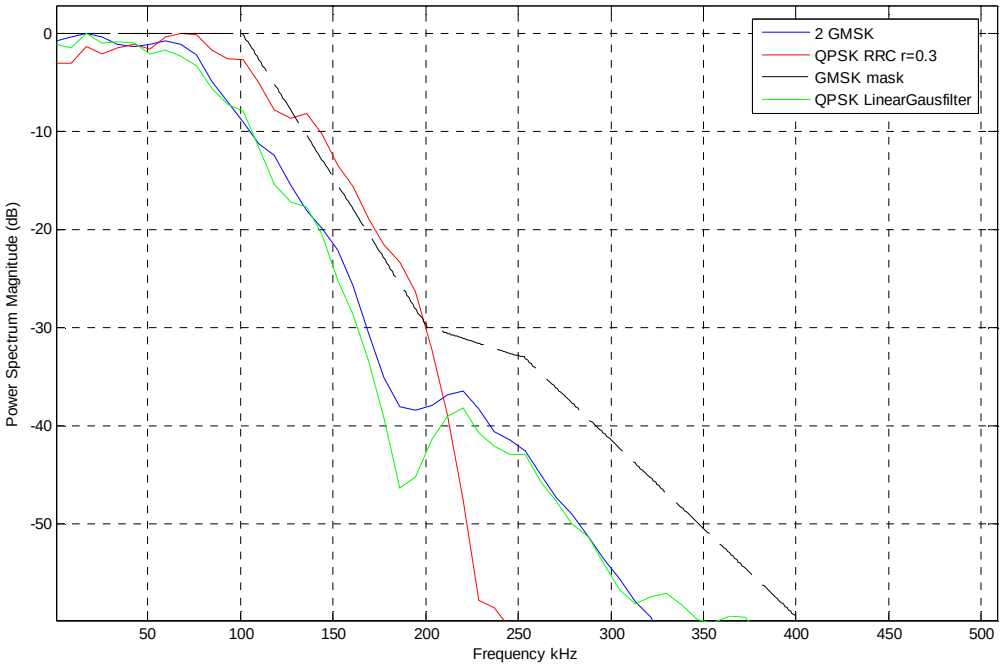

Figure 6-4 Spectrum analysis for three MUROS DL signal modulation schemes

The plots in Figure 6-4 show:

1. QPSK with RRC filter (roll off 0.3) spectrum is 10 dB higher than the GMSK spectrum between 140-200 kHz, which could have advert effect for capacity enhancement. It is also wider than the spec defined GMSK mask for useful part of the burst, and will increase ACI interference.

2. The linear combination of two GMSK signals has the same spectrum (curve overlapping) as normal GMSK signals as expected. It is within the spec defined GMSK mask for useful part of the burst.

3. QPSK with Linear Gaussian filter (8PSK pulse shaping) is similar to GMSK.

Based on these observations, it is proposed that two GMSK linear combination and QPSK with Linear Gaussian filter should be the candidates for MUROS DL modulation scheme.

6.1.2.3 Different power levels between two desired users

It has been found that when the two desired signal have different RF strengths, non-zero crossing can be achieved. For example, linear combination of two GMSK signals with different separation angles the IQ plots are as shown in Figure 6-5.

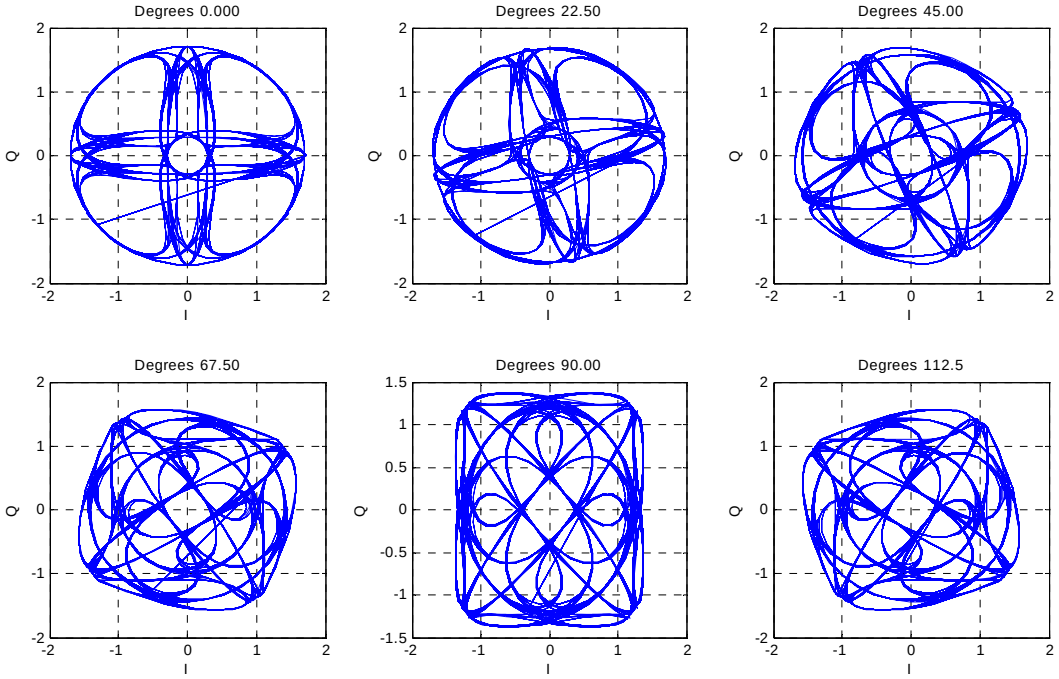

Figure 6-5 I-Q plots for linear combination of two GMSK signals with different phase separation and 3dB power difference between the two MUROS signals

This could be very useful for pairing a high performance DARP phone with a non-DARP phone. We propose to use 90 degrees phase separation as simulation showed that this achieves the best performance for two MUROS users.

6.1.3 Power control in co-TCH MUROS operation

In MUROS mode the power given to each user is based on their need, provided that the power difference is within a suitable range (i.e. 10dB) to provide sufficient signal quality for reliable reception by each mobile. As an illustration of the MUROS concept based on DARP phase I mobile we can consider the MUROS DL signal as a linear sum of two independent GMSK modulated signals. Further more the modulation can be done at baseband as shown in Figure 6-6 below. Each baseband GMSK modulated signal is individually power controlled by their gains (sinα and cosα) and added together at baseband with relative phase reference of π/2. Then the MUROS baseband signal is modulated with the carrier as MUROS DL RF signal with a gain of G.

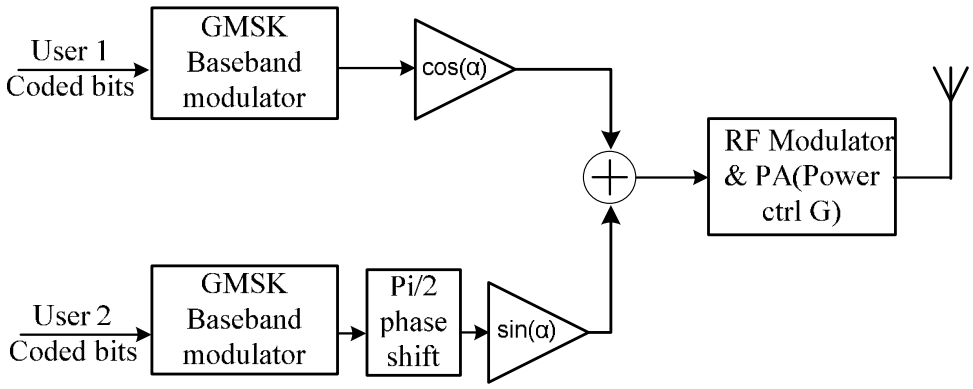

Figure 6-6: MUROS signal format concept with sub user power control

6.1.4 BTS changes for co-TCH MUROS operation

For baseband modulation the following changes are required:

Input port needs to have optional second voice channel, so that two voice streams can be modulated to form MUROS DL signals.

The baseband modulator must be able to handle one- and two-channel binary stream. The one-channel is the same as before. The two-channel function is needed when MUROS mode is on, so that the RF output is effectively two legacy RF signals, possibly of different power levels, linearly added together with one rotated by 90 degree.

There are various ways of implementing the above requirements. In the examples given below BTS needs the following two key parameters when sending downlink RF bursts in MUROS mode:

1. IQ stream of normalised scale, which suits the resolution and dynamic range of the DAC, and
2. Appropriate power level of the burst, which drives the PA.

Here is an example what MUROS BTS needs to do based on Figure 6-6:

1. From the path-loss of each of the two co-TCH mobiles, derive the required power level P1 for user 1 and P2 for user 2. Both P1 and P2 are linear quantities.
2. Using P1 and P2, obtain the IQ amplitude ratio of the two users as follows: $R = \sqrt{P2/P1}$ (P1>0, P2>0).
3. Determine the digital gains for each of the two co-TCH mobiles:
   For user 1, G1 = cos(α), and

   For user 2, G2 = sin(α),

   where α=arc tan(R) and $\alpha \in [0, \pi/2]$
4. Decide the Tx RF gain for the PA so that the Tx power level is
   P=P1+P2

Another example of achieving the same effect is:

1. Align the two busts, and map user 1 and 2"s burst level coded bits to I and Q respectively. On I-axis 0→kG1, 1→-kG1. On Q-axis 0→kG2, 1→-kG2, where k is a scalar factor represents G1 and G2 in fix point format with a satisfactory resolution.

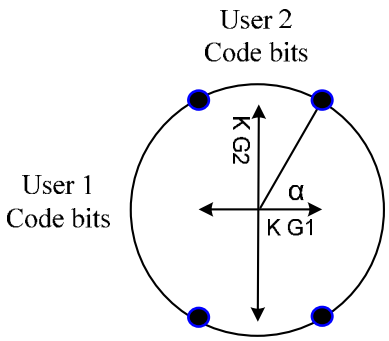

Figure 6-7: Map two users" *i*th bits on to QPSK considering power control of both users

2. Apply Pi/2 phase rotation on every symbol progressively (just like EGPRS 3Pi/8 rotation on every symbol).
3. Apply Gaussian linear filter to satisfy the GSM spectrum mask.

Both of the above approaches give the same spectrum. Simulations based on both above schemes have the same performance.

Examples of baseband IQ trajectory have been described in section 6.1.2.3.

In the case of one mobile in DTx mode, the corresponding gain control (G1 or G2) is simply set to 0 (in linear term, not dB) while the other gain control is set to 1. If both users are in DTx mode then both gain controls are set to 0.

6.2 Performance Characterization

6.2.1 Link Level Performance

The performance of a DARP Phase 1 receiver is evaluated under the various configurations defined in chapter 5. The legacy training sequence set and the Nokia training sequence (section 10.1.1) set was used in these simulations. A MUROS capable mobile is assumed to support new training sequence codes, in this case the new TSC set proposed in section 10.1.1. The legacy DARP Phase 1 mobile is assumed to support the legacy TSC set.

Configuration for link level simulations

The simulation configuration for MTS and sensitivity scenarios is shown in Table 6-1 below. In this configuration both co-TCH users have the same power level.

Table 6-1 Link level simulation configuration for MTS scenarios

Parameter	Value
MUROS Test Scenario	MTS-1, MTS-2, MTS-3, MTS-4 and Sensitivity
TSC	NSN 4 (desired) and Legacy 4
Audio Codec	GSM HR, GSM FR, AFS 12.2, AFS 5.9 and AHS 5.9
Frequency Hopping	Ideal Hopping and without hopping
Propagation environment	TU3 and TU50
DTX	Not used
Interferer Modulation	GMSK

6.2.1.1 Sensitivity performance

The link level sensitivity performance of MUROS (two user relative power of 0dB) is shown with and without ideal frequency hopping where it applies. However it should be noted that with restricted bandwidth the frequency hopping improvement can be far less.

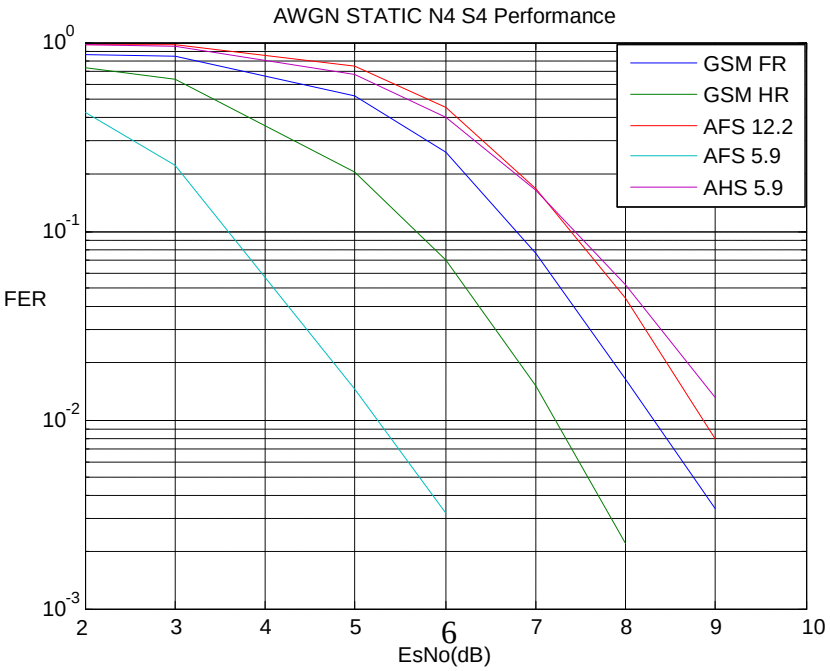

Figure 6-8: DARP Phase 1 mobile performance in sensitivity condition with static channel

This shows a good performance in static AWGN case, where mobile station can work in most places in a cell with conventional cell planning.

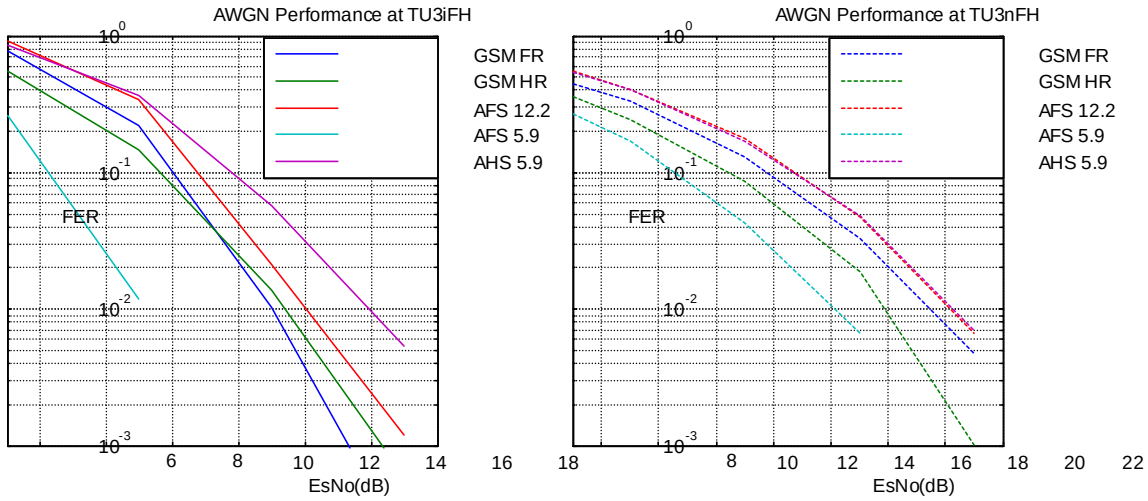

Figure 6-9: DARP Phase 1 mobile performance in sensitivity condition with TU3

The results show, as expected, that TU3 introduces 10dB degradation to static case, a major impact to sensitivity performance. However ideal FH improve it by 5 to 7dB.

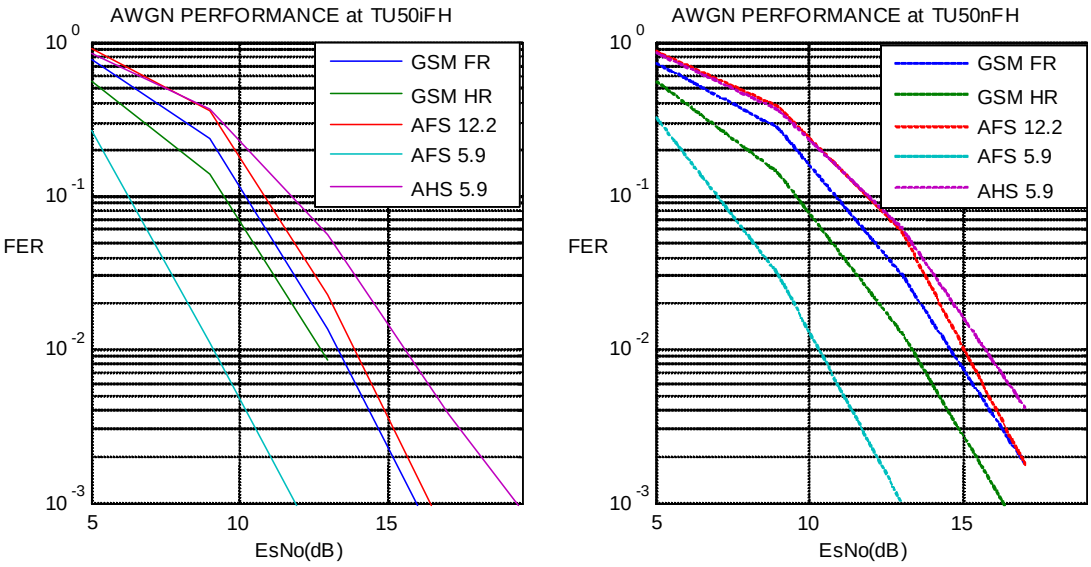

Figure 6-10: DARP Phase 1 mobile performance in sensitivity condition with TU50

TU50 introduces 5 to 7 dB degradation to static case and ideal FH improves by 1 dB, not as much as with TU3.

The conclusion is that MUROS works well in static condition but will have 10dB degradation for worst fading channel which means TU3 does need frequency hopping.

6.2.1.2 Interference performance

6.2.1.2.1 MTS-1 configuration

The link level performance for MTS-1 configuration is shown in Figure 6-11 and Figure 6-12.

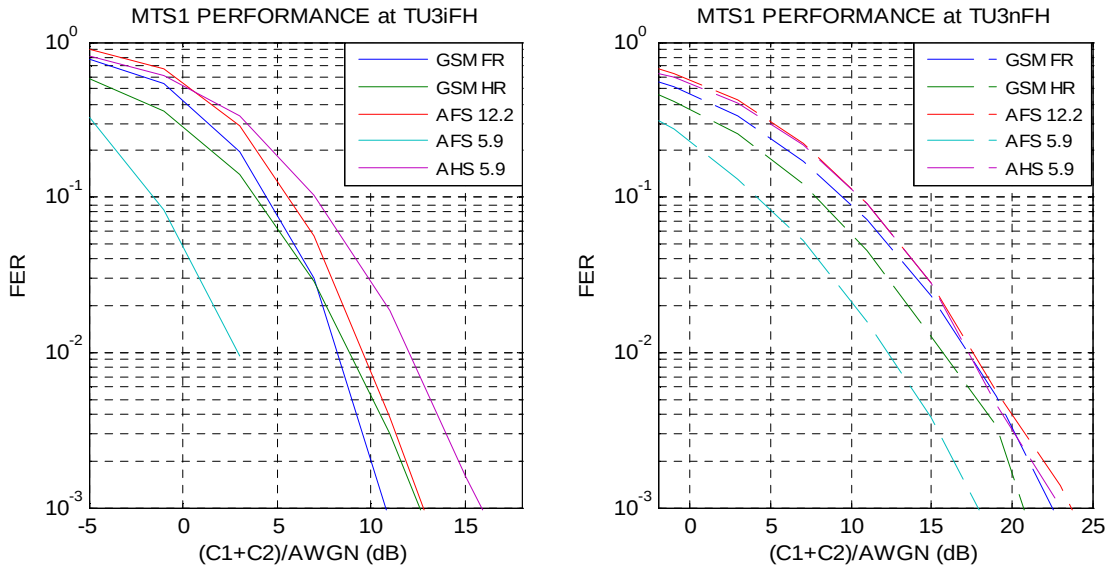

Figure 6-11 DARP Phase 1 mobile performance in MTS-1 scenario with TU3

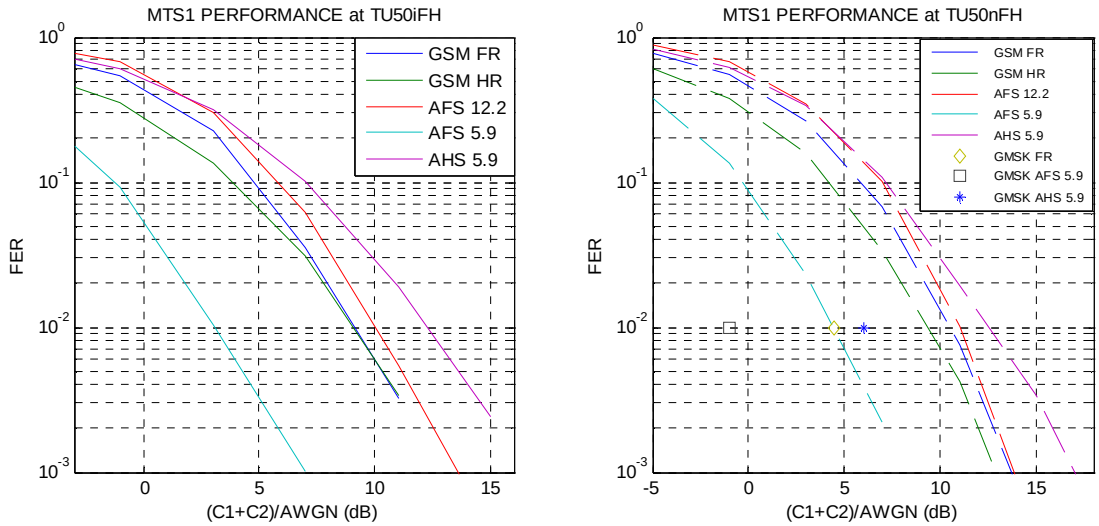

Figure 6-12: DARP Phase 1 mobile performance in MTS-1 scenario with TU50

The spec point for a DARP Phase 1 receiver with GMSK modulated signal is also shown on the second graph in Figure 6-12. As can be seen that the performance of a DARP Phase 1 receiver with MUROS signal is around 3-4dB worse for GSM FR, AFS5.9 and AHS5.9 codecs with iFH, which is reasonable as two users are supported simultaneously by the same radio.

It is clear that even in MUROS mode DARP mobile can still suppress CCI by further 4 to 6 dBs compared with AWGN as MTS-1 has coloured noise.

As expected with ideal frequency hopping, both TU3 and TU50 performing equally well. Without frequency hopping, on the other hand, TU3 degrades by 6 to 10 dB, and TU50 by 2 dB compared to the static case.

6.2.1.2.2 MTS-2 configuration

The link level performance for MTS-2 configuration is shown in Figure 6-13 and Figure 6-14.

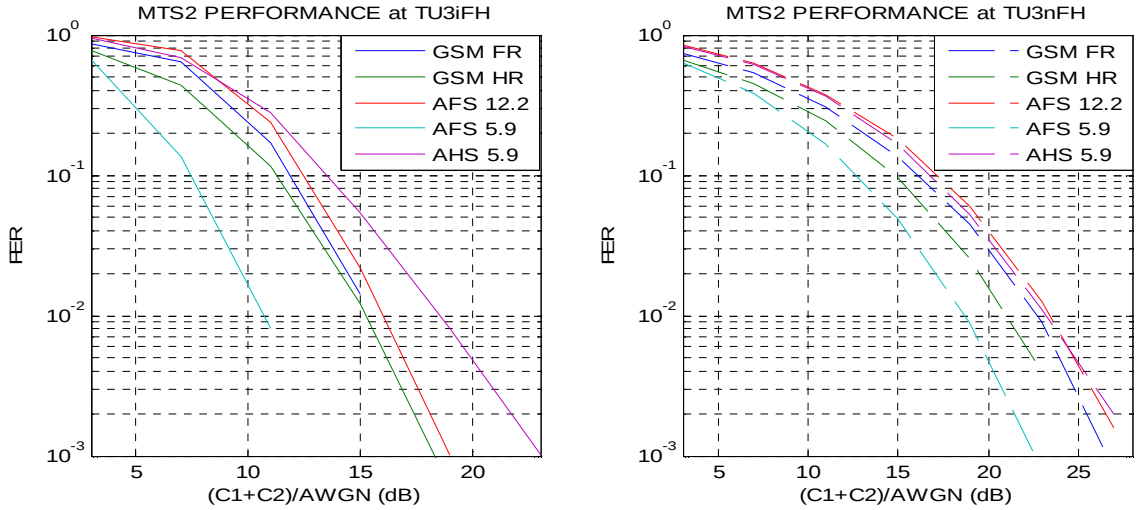

Figure 6-13: DARP Phase 1 mobile performance in MTS-2 scenario with TU3

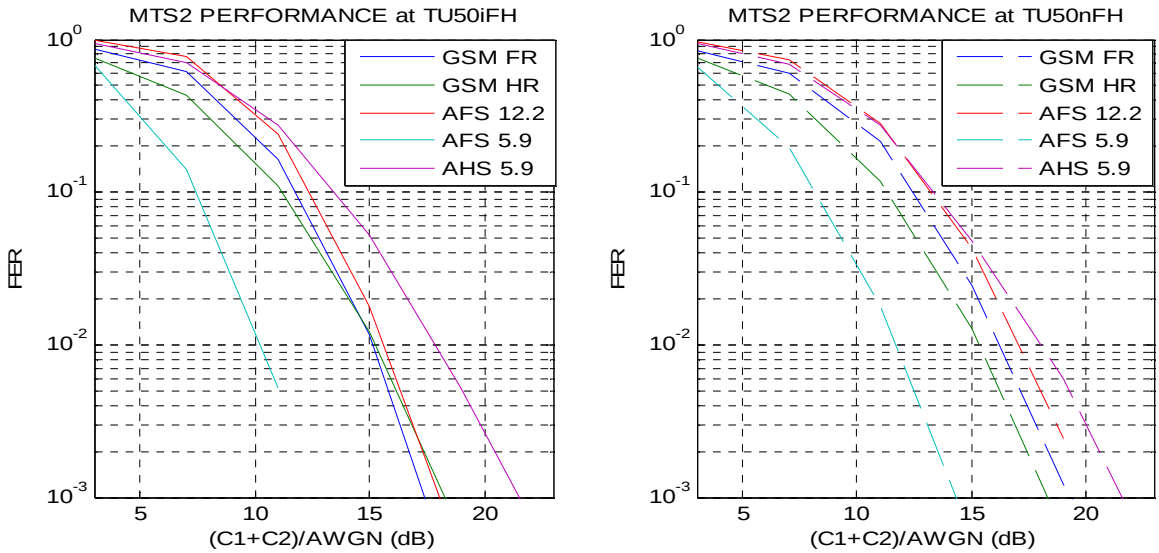

Figure 6-14: DARP Phase 1 mobile performance in MTS-2 scenario with TU50

The results show that MTS-2 is about 1 to 2 dB worse than AWGN, this means that when the interference type is mixed CCIs and ACIs, it is even harder than AWGN for DARP receiver to deal with. As usual, iFH would provide 4 to 9 dB improvement in TU3 channel.

6.2.1.2.3 MTS-3 configuration

The link level performance for MTS-3 configuration is shown in Figure 6-15 and Figure 6-16.

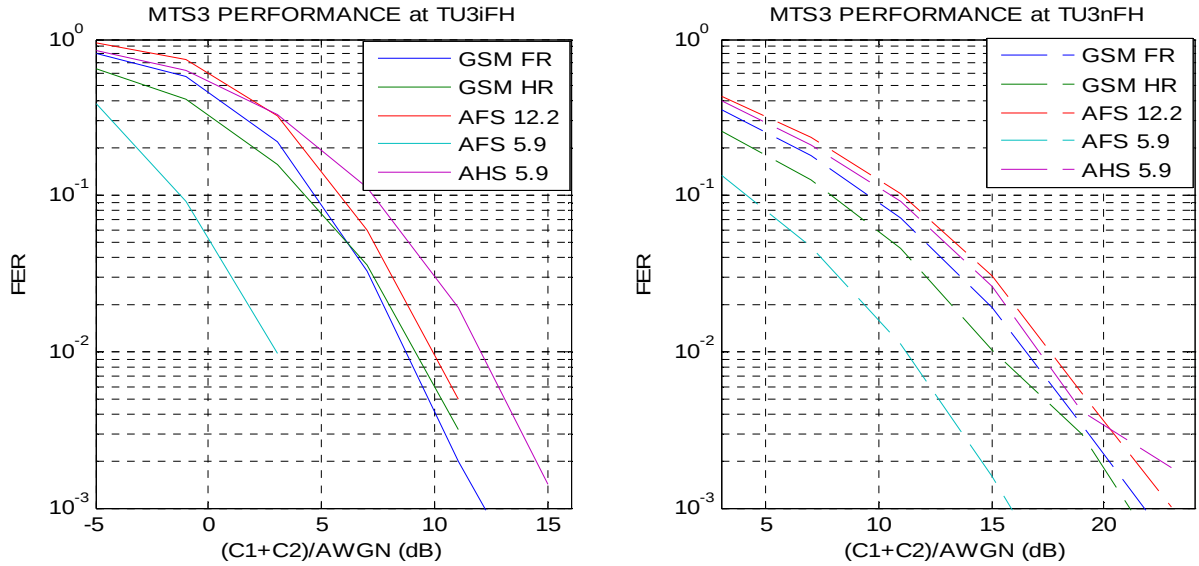

Figure 6-15: DARP Phase 1 mobile performance in MTS-3 scenario with TU3

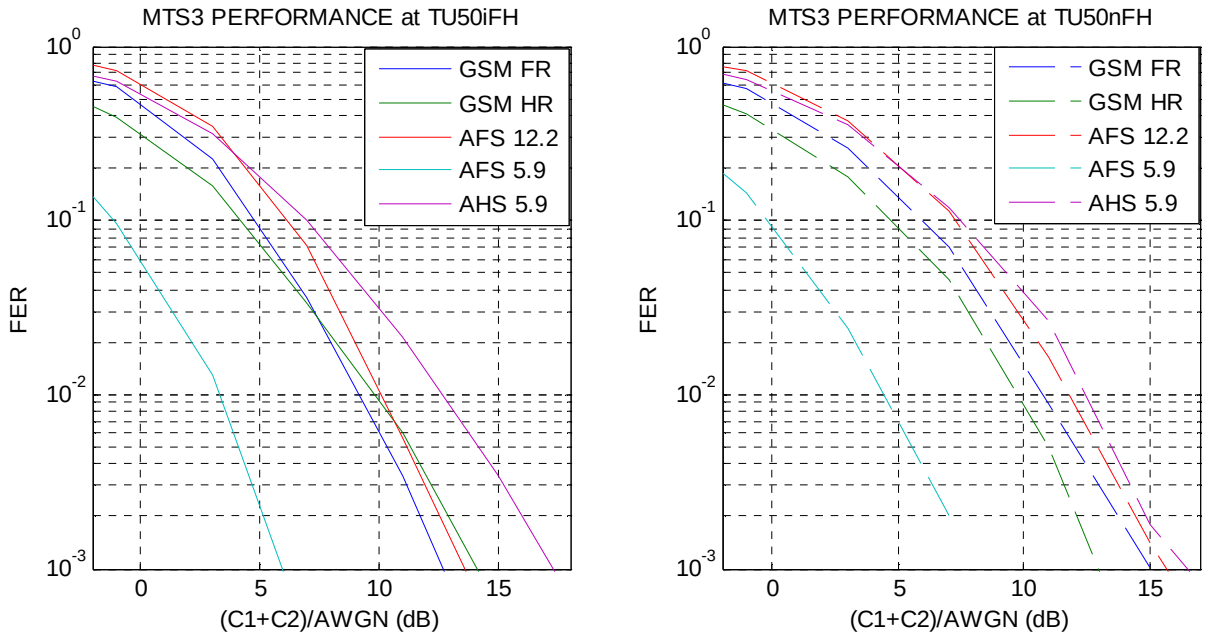

Figure 6-16: DARP Phase 1 mobile performance in MTS-3 scenario with TU50

The link level results for MTS-3 are similar to MTS-1 for our receiver implementation.

6.2.1.2.4 MTS-4 configuration

The link level performance for MTS-4 configuration is shown in Figure 6-17 and Figure 6-18.

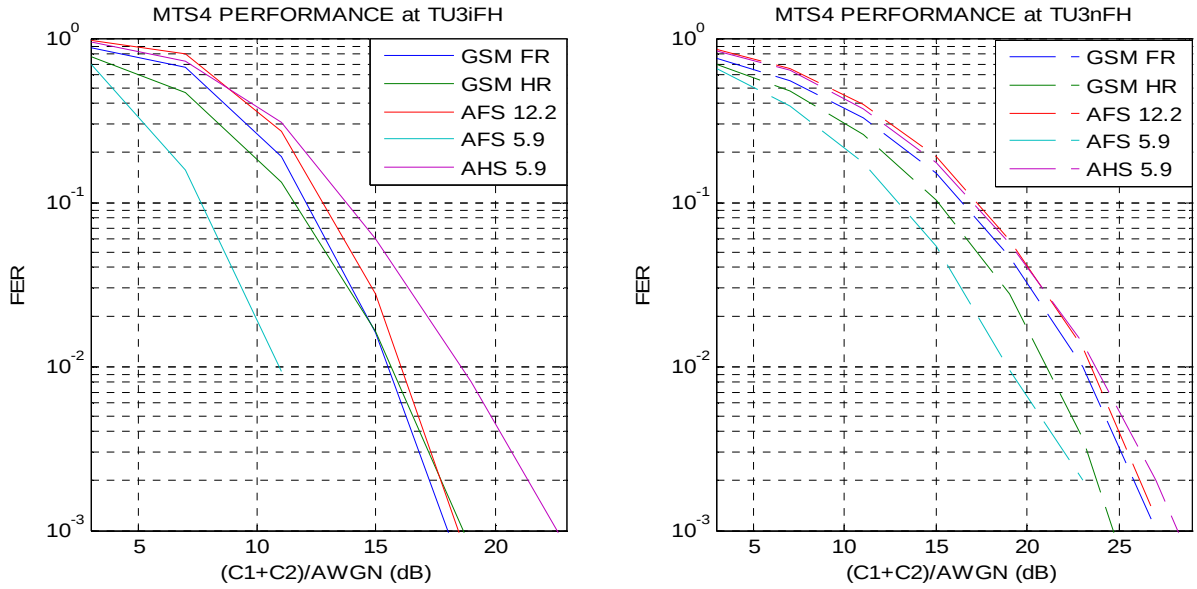

Figure 6-17: DARP Phase 1 mobile performance in MTS-4 scenario with TU3

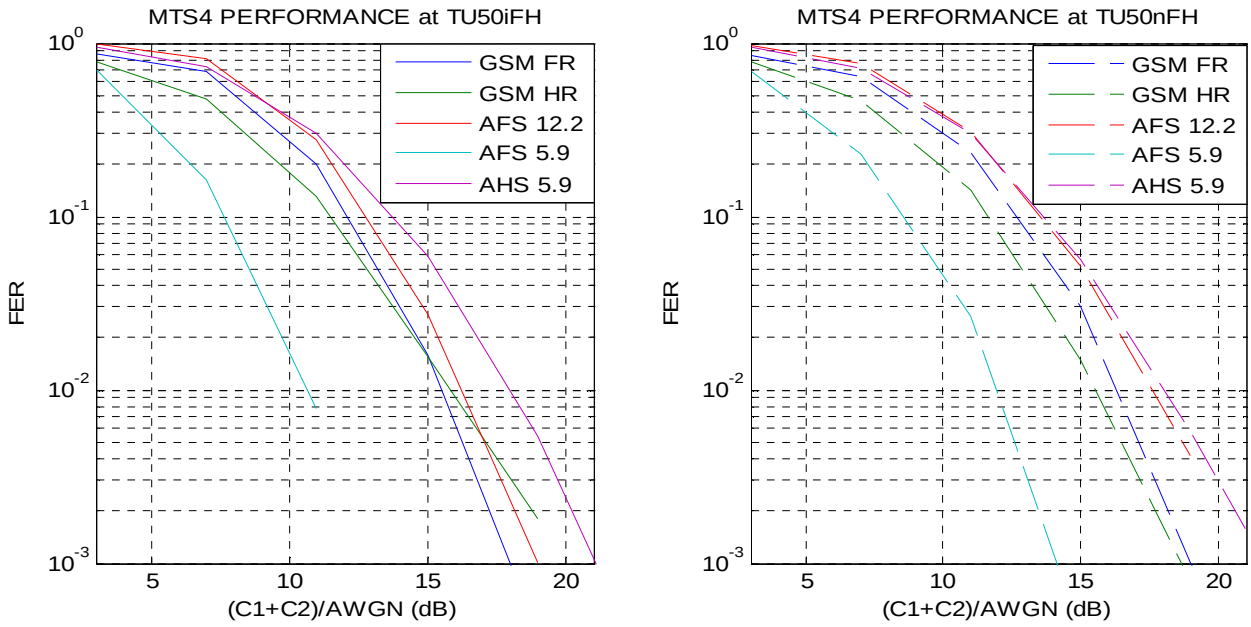

Figure 6-18: DARP Phase 1 mobile performance in MTS-4 scenario with TU50

The link level results for MTS-4 are similar to MTS-2 for our receiver implementation.

6.2.1.3 Link level performance with power imbalance

This section shows the link level performance with power imbalance for the two co-TCH users. Following effects have been studied:

1. On both paired users, both DARP with DARP and DARP with non-DARP;
2. The different TSCs;
3. Two codecs of AFS5.9 and HR;
4. Different fading channels, including TU50 with iFH;
5. Different cases of sensitivity and MTS1;

The configuration for the link level simulation is shown in Table 6-2.

Table 6-2: Link level simulation configuration for power imbalance scenarios

Parameter	Value
MUROS Test Scenario	Sensitivity and MTS1
TSC	NSN 4 and legacy TSC 4
Audio Codec	AFS 5.9 and HR
Frequency Hopping	with hopping
Propagation environment	AWGN and CCI
DTX	Not used
Power imbalance (dB)	0, 2, 4, 6, 8 and 10 for the legacy MS -2, -4, -6, -8 and -10 for the DARP MS

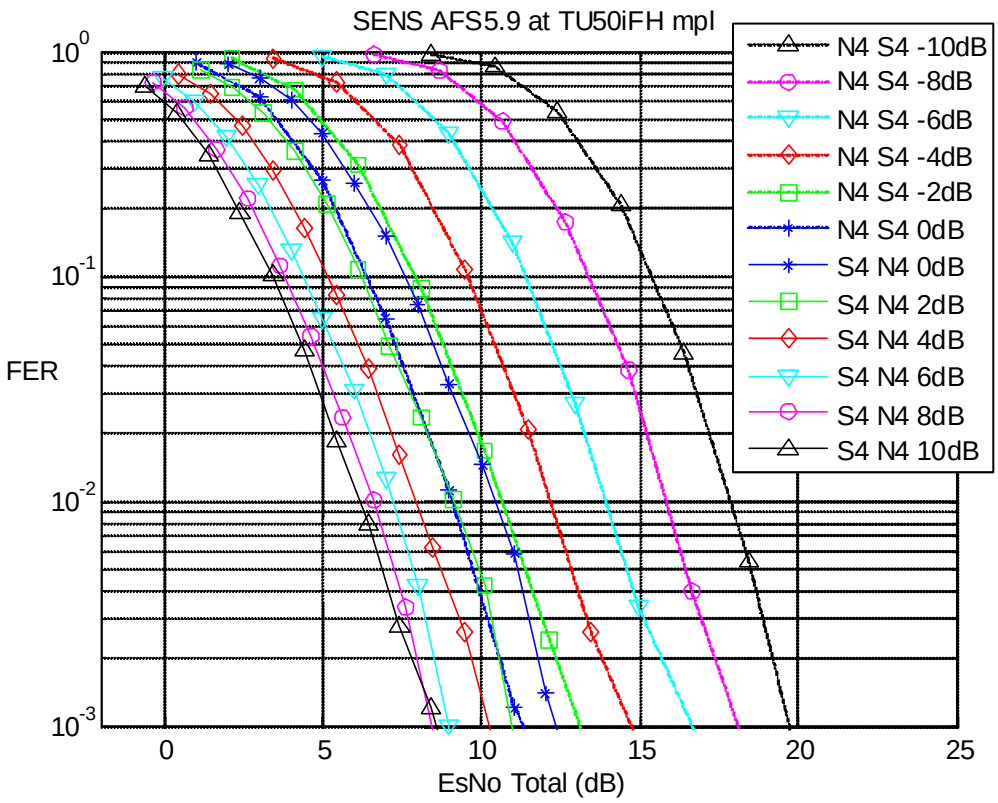

Figure 6-19: MUROS mode performance of DARP mobile with power imbalance in AWGN (AFS 5.9)

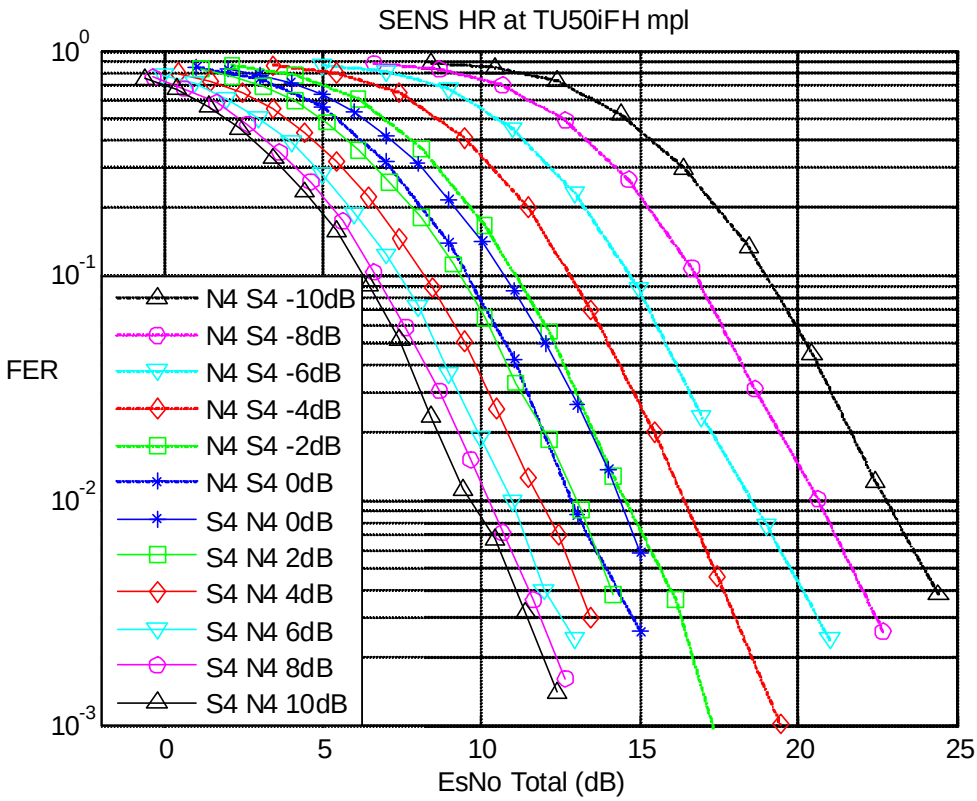

Figure 6-20: MUROS mode performance of DARP mobile with power imbalance in AWGN (GSM HR)

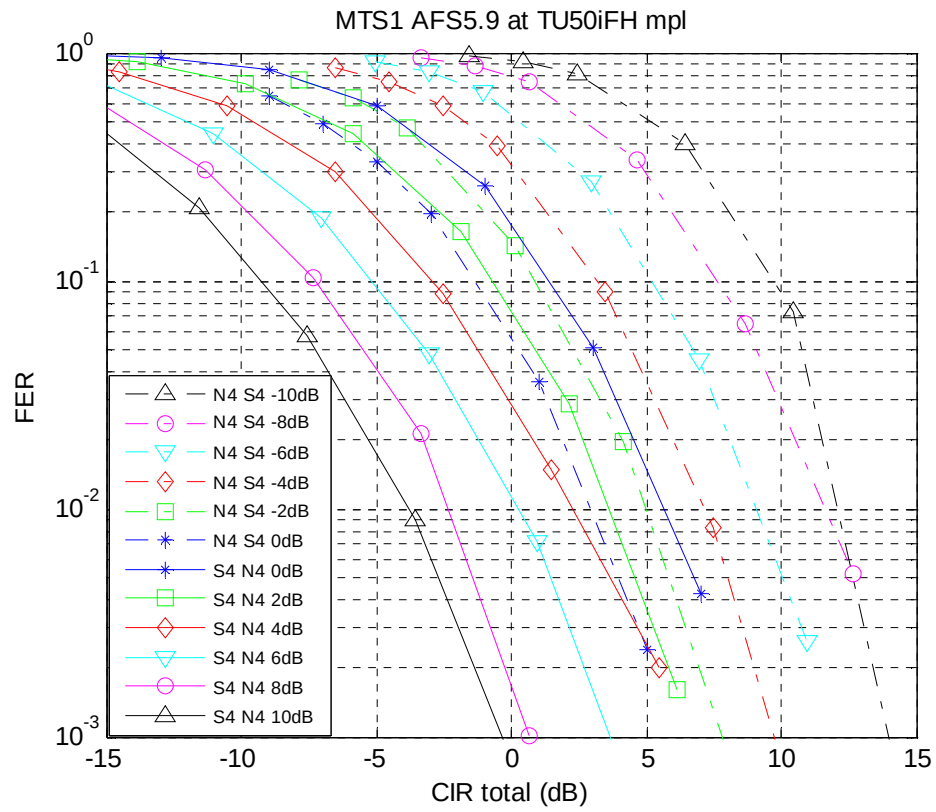

Figure 6-21: MUROS mode performance of DARP mobile with power imbalance in MTS1 (AFS 5.9)

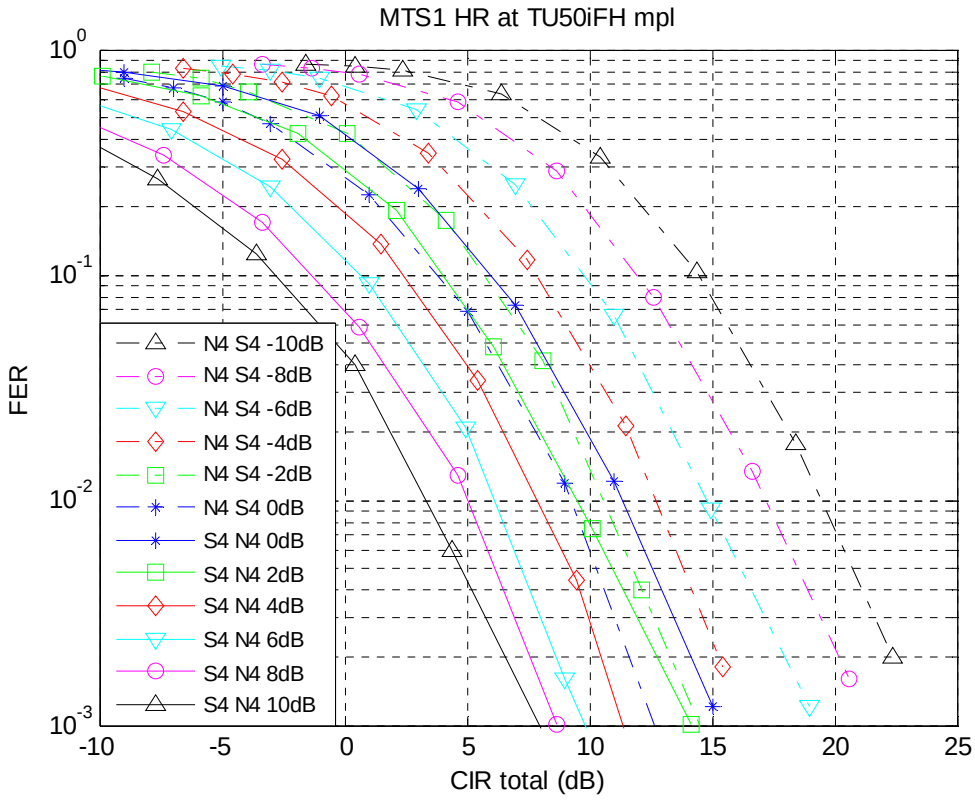

Figure 6-22: MUROS mode performance of DARP mobile with power imbalance in MTS1 (GSM HR)

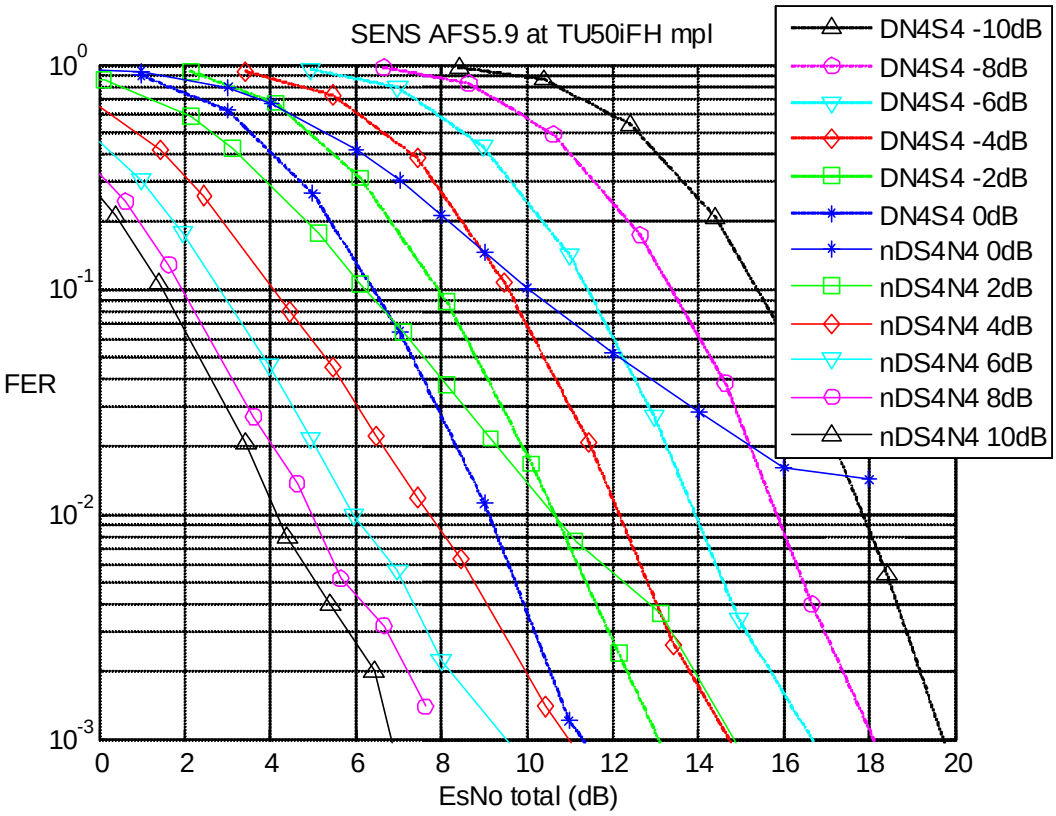

Figure 6-23: MUROS mode performance of DARP mobile with power imbalance in AWGN (AFS5.9)

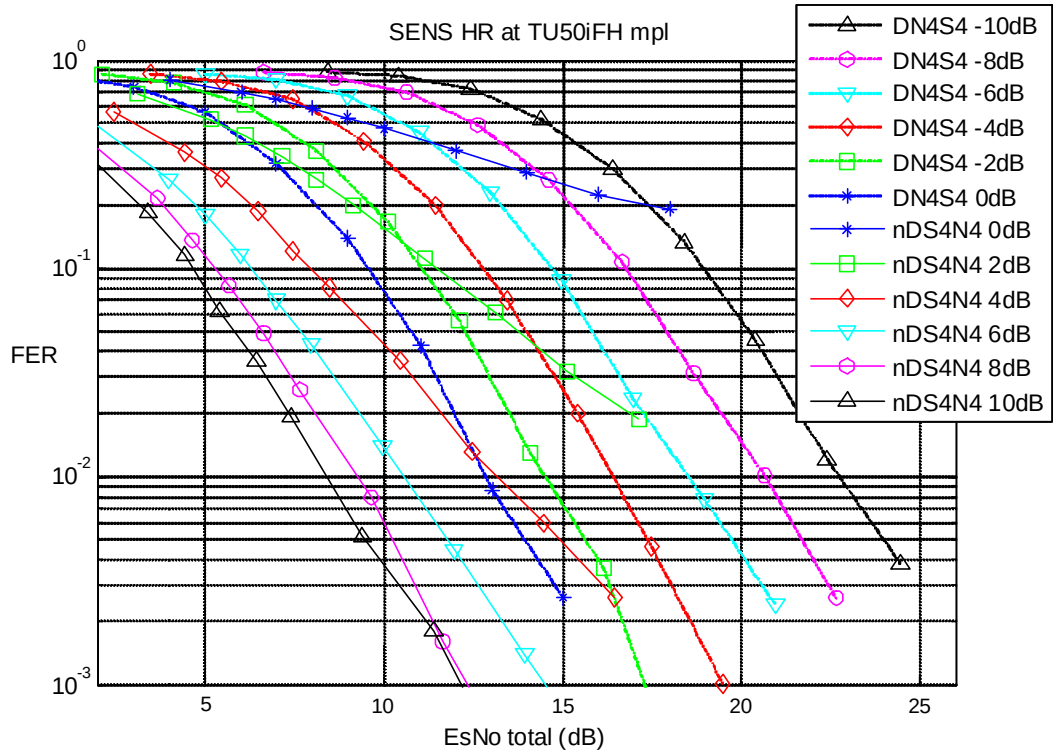

Figure 6-24: MUROS mode performance of DARP mobile with power imbalance in AWGN (GSM HR)

6.2.1.4 SACCH performance on MUROS and non-MUROS

Signalling is an important part of MUROS operation. SACCH has a special importance for maintaining the radio link for voice service. For the purposes of comparison, SACCH performance for non-MUROS and MUROS are studied with reference to five other codecs here.

6.2.1.4.1 Non-MUROS and MUROS Sensitivity Performance

Figure 6-25 shows SACCH performance simulated with non-MUROS (Con.) and MUROS (0dB) modes in static, TU50 and TU3 channels with ideal frequency hopping.

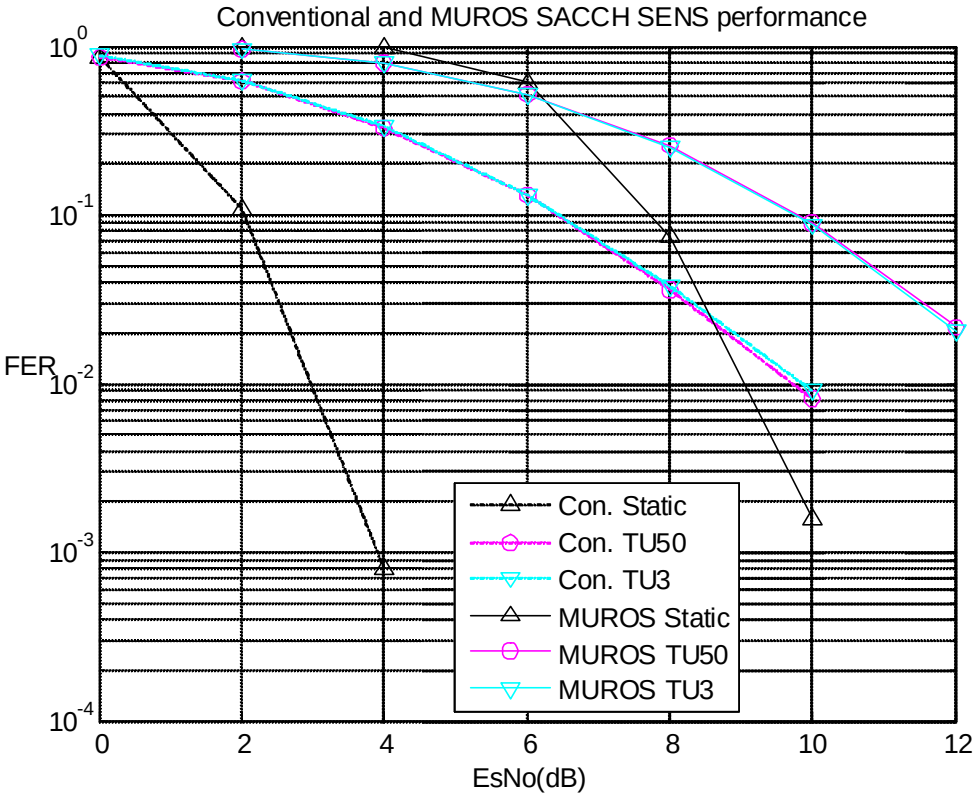

Figure 6-25: DARP Phase 1 mobile SACCH sensitivity performance with static, TU3, TU50 channels and iFH on non-MUROS and MUROS (C1/AWGN)

Firstly, as expected with ideal FH, TU3 and TU50 are about the same.

Secondly, SACCH does not have strong FEC, and can degrade pretty quickly with poor RF conditions. This is shown by

1. The 7 dB degradation from static to TU channel in non-MUROS mode.
2. The 6dB degradation on static channel from non-MUROS to MUROS mode.
3. The 3 dB degradation from non-MUROS to MUROS mode on TU channel (with ideal frequency hopping).

For comparison with the non-MUROS case, Figure 6-25 has been plotted without considering the total power, which would be 3 dB more for this case.

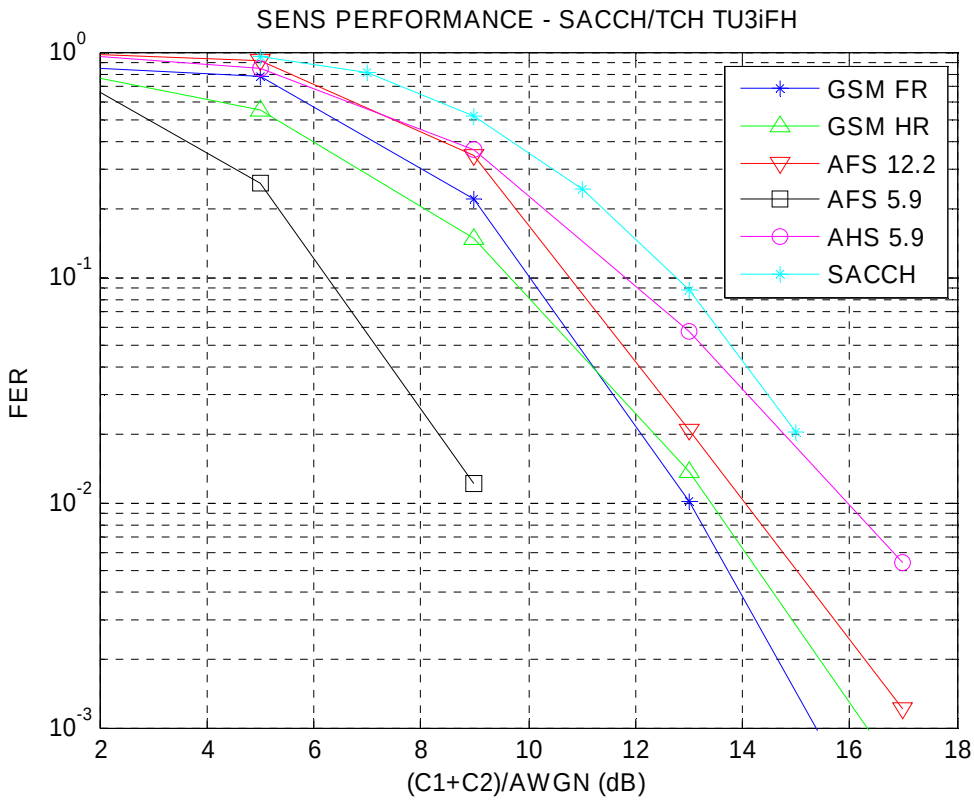

Figure 6-26: DARP Phase 1 mobile MUROS (0dB) SACCH/TCHes performance comparison in TU3 iFH

For comparison of SACCH and TCH"s Figure 6-26 shows that SACCH with equal power MUROS for the pair would perform slightly worse than AHS5.9, and more than 6 dB worse than AFS5.9. This means that

1. MUROS mode, as expected, near the cell edge is generally not as good as close to the cell centre.
2. If MUROS is used in sensitivity limited case, on AFS, SACCH could be the weakest link. Alternative power imbalance and repeated SACCH would be helpful with 4 to 5 dB gain.
3. SACCH sensitivity performance is similar to AHS5.9 in MUROS mode (15 dB EbNo).

It is expected that HS and AHS are going to be the main focus on MUROS mode and the above shows that it should fine for DARP phone working in MUROS mode when they are not near the cell edge.

6.2.1.4.2 Non-MUROS and MUROS Interference Performance

To understand the relative performance degradation between voice codecs and SACCH in non-MUROS and MUROS mode, DTS-1, DTS-2, MTS-1 and MTS-2 are simulated at link level for five codecs and SACCH. Furthermore, link level simulation results for SACCH, AFS5.9 and AHS5.9 in DTS-1 and DTS2 scenarios have been verified in the lab. All link level MUROS simulations were performed 0dB power imbalance.

In the figures below, the RF conditions are normalised to SACCH 2% FER point in order to see the relative performance of five codecs in both non-MUROS (i.e. DTS) and MUROS (i.e. MTS) modes.

Note that the SACCH performance in each case will be the same irrespective of the speech codec.

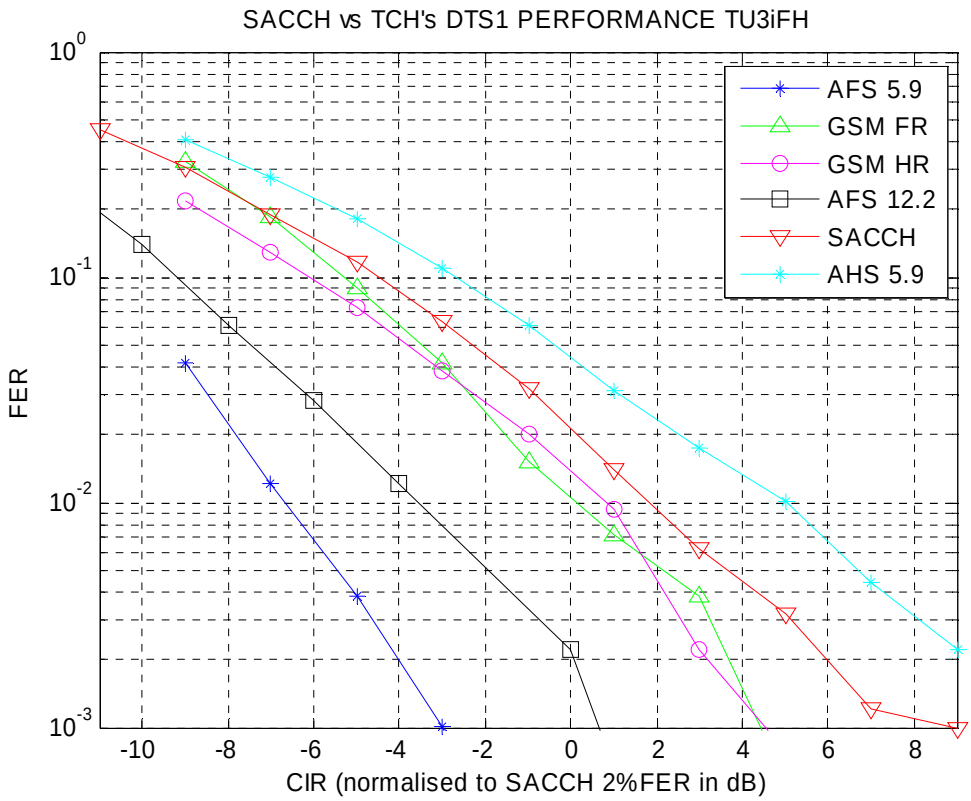

Figure 6-27: DARP Phase 1 mobile SACCH/TCH"s performance in DTS-1 scenario with TU3 iFH

In non-MUROS mode, with just one CCI (DTS1), SACCH performance is only 3 dB better than AHS5.9, but worse than other codecs listed above. However for HR it is only about 1 dB worse. This shows the same conclusion: SACCH cannot match some of the good AFS codecs. So in such cases repeated SACCH would be very helpful, as 4 to 5 dB gain can be obtained.

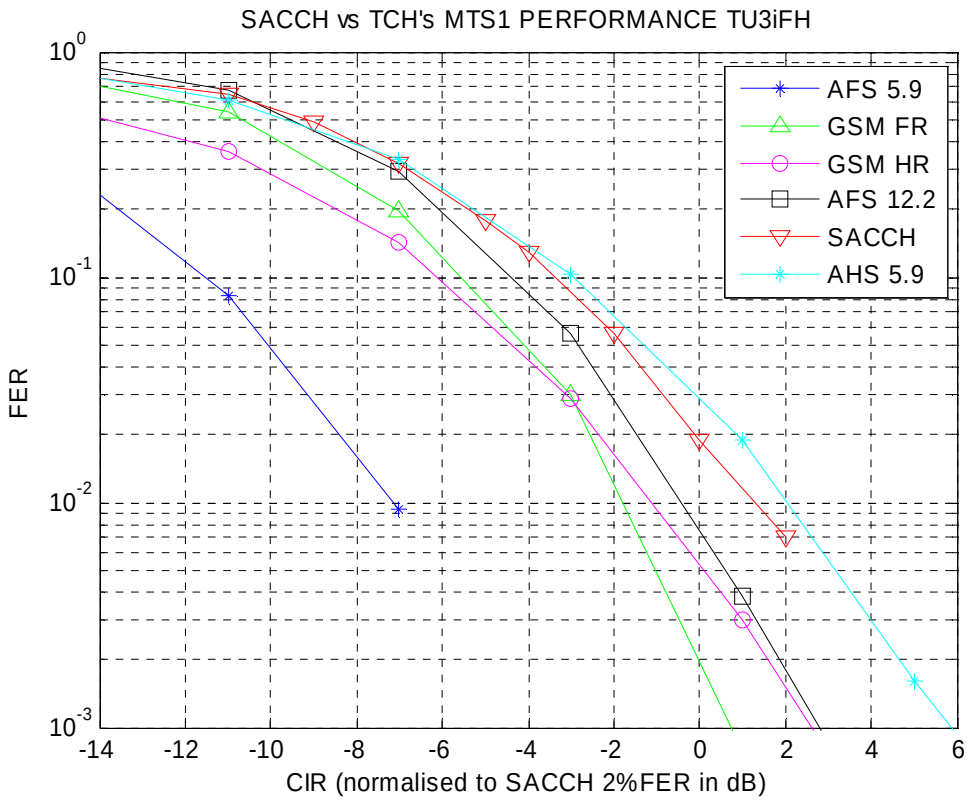

Figure 6-28: DARP Phase 1 mobile SACCH/TCH"s performance in MTS-1 scenario with TU3 iFH

In the case of MUROS (0dB pairing) MTS1, SACCH performance stays relatively the same (or slightly worse) to other codecs with regards to DTS1. This means that there is no new SACCH issue when MUROS mode is used. In both MTS1 and DTS1 repeated SACCH would help. Compare with AHS5.9 and HR it is not going to cause major issue if RRC does good job on selecting the MUROS pair in the first place.

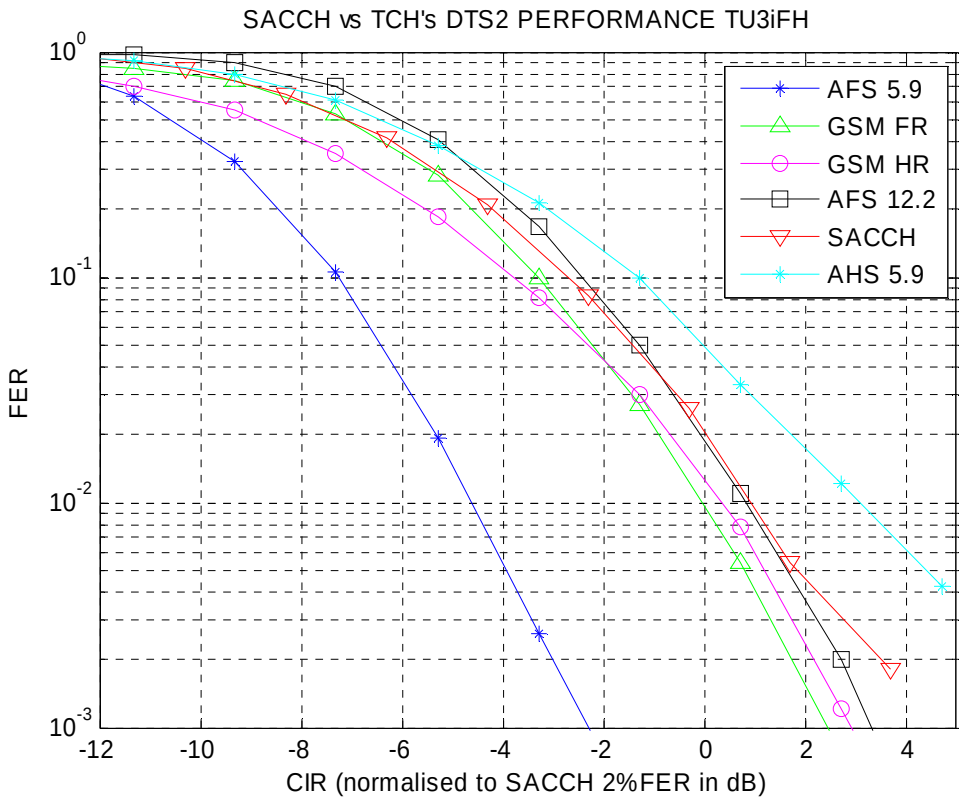

Figure 6-29: DARP Phase 1 mobile SACCH/TCH"s performance in DTS-2 scenario with TU3 iFH

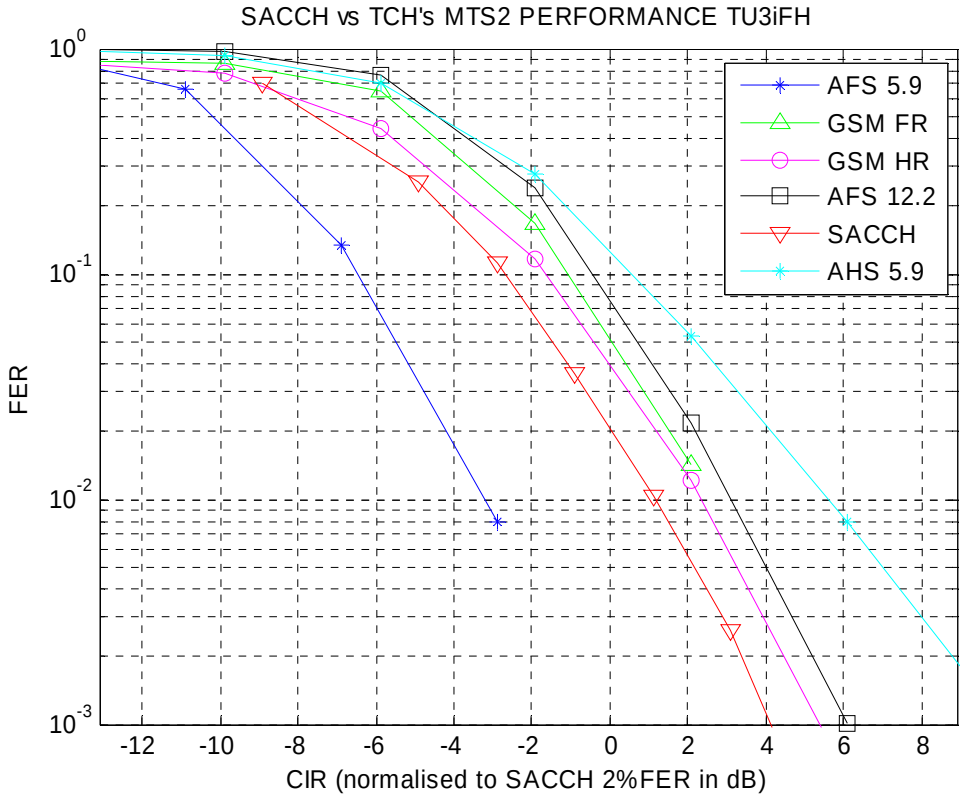

Figure 6-30: DARP Phase 1 mobile SACCH/TCH"s performance in MTS-2 scenario with TU3 iFH

When comparing DTS2 with MTS2, SACCH performance seems better relatively to other codecs in MTS2 than DTS2. This is due to the case that DTS2 and MTS2 is not a good case for DARP to perform, and all codecs performance drop more than SACCH, as SACCH does not have very good FEC anyway to take the advantage of better condition.

This shows that in non-MUROS mode (i.e. DTS-2) the SACCH performance is about 6 dB worse than the AFS5.9, while in MUROS mode (i.e. MTS2) it is about 4 dB worse than AFS5.9, and becomes better than other four codecs listed above.

Although SACCH may be the weak link, the condition under which MUROS can perform well would have this condition anyway.

It is clear that SACCH performance is not as good as performance of some AMR codecs. But if MUROS is going to be used with HR and AHS, then SACCH is about the same performance and should be fine. In case SACCH needs to be improved, following method can be used:

1. Repeated SACCH could give 4 to 5 dB gain.
2. Alternatively giving high power for SACCH could be used to help the one in trouble.
3. Time offset of SACCH frame between neighbor cells to avoid SACCH shouting together. This could help in this case of synchronized network.

It is also true that SACCH should not be expected to be the same performance in order to maintain the voice service. It has a wider range of acceptance by the network.

6.2.2 Network Level Performance

6.2.2.1 System Setup and Configurations

The performance of a DARP Phase 1 receiver [6-2] is evaluated via system simulations for the various configurations and working assumptions defined in this TR. The system simulator provides snapshot system performance using a 19 site, 3 cells/site wraparound layout. The simulator completely models both fast and slow fading between each receiver and transmitter. However the simulator does not model mobility and handoff. The simulation results should be interpreted as average snapshot system performance for that particular configuration.

The system parameters of interest are reproduced below in Table 6-3.

Table 6-3: Different network configurations for MUROS system simulations

Parameter	*MUROS-1*	*MUROS-2*	*MUROS-3A*	*MUROS-3B*
Frequency band (MHz)	900	900	1800	1800
Cell radius	500 m	500 m	500 m	500 m
Bandwidth	4.4 MHz	11.6 MHz	2.6 MHz	2.6 MHz
Guard band	0.2 MHz	0.2 MHz	0.2 MHz	0.2 MHz
# channels excluding guard band	21	57	12	12
# TRX	4	6	4	4
BCCH frequency re-use	4/12	4/12	N.A.	N.A.
TCH frequency re-use	1/1	3/9	1/3	1/1
Frequency Hopping	Synthesized	Baseband	Synthesized	Synthesized
Length of MA (# FH frequencies)	9	5	4	12
Fast fading types	TU 50 / TU 3	TU 50 / TU 3	TU 50 / TU 3	TU 50 / TU 3

6.2.2.1.1 Enabled features for system simulations

The system simulation was run with the following features included:

Table 6-4: Common configuration parameters for all MUROS modes

Feature	Description
Modulation	GMSK (single user), 2-GMSK (MUROS mode)
Audio Codecs	GSM HR, AFS 12.2, AFS 5.9 and AHS 5.9
Frequency Hopping	Randomized (for both Synthesized and Baseband hopping modes)
DTX	60% voice activity period
Antenna pattern	Both 65° and 90° 3dB antenna bandwidth as agreed in GERAN Telco#5
Transmission on BCCH ARFCN	BCCH Frequency is used only for transmission to users with low RXQUAL on TCH; MUROS is not enabled on BCCH
Power Control	Sub-channel specific power adjustment.
MS Receiver Type	For y% penetration of MUROS case, y% : DARP Phase 1, MUROS aware 0.7 (100-y)%: DARP Phase 1 (not MUROS aware) 0.3 (100-y)%: non-DARP Phase 1

For the different scenarios, the system was simulated to determine the maximum number of supportable channels per sector satisfying the FER criterion specified in this TR. The voice call arrival process as specified in this TR is separately accounted for to determine the Erlang capacity. In case of 100% penetration, there is only a single queue of users and the relation between maximum number of supportable channels and Erlang capacity is given by the following equation:

$$B_\rho = \frac{(\rho)^N / N!}{\sum_{i=0}^{N} (\rho)^i / i!},$$

where ρ is the Erlang capacity, N is the number of voice channels that can be supported without violating FER constraints (obtained through simulation), and B_ρ is the blocking probability. Erlang capacity is determined for $B_\rho = 0.02$. In case of less than 100% penetration, there are two queues of users and the arrival process is separately simulated to determine the Erlang capacity based on maximum number of supportable users determined using system simulations.

This approach is relatively simple and has merits over modeling the arrival and departure process in system simulations which are already computationally and memory intensive. Since the mean voice call service time is 90 seconds, simulations would need to be run for extremely long durations to reliably model the statistical arrival/departure processes and to average out the short-term statistical variations. Otherwise the results can be greatly affected by simulation noise.

6.2.2.1.2 Simulated Channel Mode Adaptations

Maximum system capacity was determined for each audio codec in both single-user and MUROS modes. For the current set of results being presented, dynamic codec/rate adaptation was not considered.

Table 6-5 Channel mode definitions

Channel Mode Adaptation	Description
Type A0	GSM HR for single-user mode
Type A1	GSM HR for MUROS mode
Type B0	AFS 12.2 for single user mode
Type B1	AFS 12.2 for MUROS mode
Type C0	AFS 5.9 for single user mode
Type C1	AFS 5.9 for MUROS mode
Type D0	AHS 5.9 for single user mode
Type D1	AHS 5.9 for MUROS mode

6.2.2.2 Simulation Results

The criteria for minimum call quality used to determine system capacity is described in this TR. The capacity results are presented separately for TU3 and TU50 channel models and for each antenna pattern. The configurations where MUROS shows capacity gains are highlighted in green.

6.2.2.2.1 MUROS-1 with 100% penetration

6.2.2.2.1.1 TU 50km/hr channel model

Table 6-6: Simulation results for MUROS-1, TU50 with 65° Antenna

Channel Mode	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	54	35.52	10.99	Blocked calls
Type A1	81	56.24	17.40	Call quality (FER > 3%)
Type B0	27	15.56	4.81	Blocked calls
Type B1	35	21.33	6.60	Call quality (FER > 2%)
Type C0	27	15.56	4.81	Blocked calls
Type C1	51	33.25	10.29	Blocked calls
Type D0	54	35.52	10.99	Blocked calls
Type D1	58	38.59	11.94	Call quality (FER > 3%)

Table 6-7: Simulation results for MUROS-1, TU50 with 90° Antenna

Channel Mode	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	54	35.52	10.99	Blocked calls

Type B0	27	15.56	4.81	Blocked calls
Type B1	30	17.70	5.47	Call quality (FER > 2%)
Type C0	27	15.56	4.81	Blocked calls
Type C1	51	33.25	10.29	Blocked calls
Type D0	54	35.52	10.99	Blocked calls
Type D1	56	37.05	11.46	Call quality (FER > 3%)

6.2.2.2.1.2 TU 3km/hr channel model

Table 6-8 Simulation results for MUROS-1, TU3 with 65° Antenna

Channel Mode	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	54	35.52	10.99	Blocked calls
Type A1	65	43.92	13.59	Call quality (FER > 3%)
Type B0	23	12.73	3.94	Call quality (FER > 2%)
Type B1	23	12.73	3.94	Call quality (FER > 2%)
Type C0	27	15.56	4.81	Blocked calls
Type C1	40	25.01	7.74	Call quality (FER > 2%)
Type D0	46	29.49	9.13	Call quality (FER > 3%)
Type D1	46	29.49	9.13	Call quality (FER > 3%)

Table 6-9 Simulation results for MUROS-1, TU3 with 90° Antenna

Channel Mode	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	54	35.52	10.99	Blocked calls
Type A1	59	39.35	12.18	Call quality (FER > 3%)
Type B0	21	11.31	3.50	Call quality (FER > 2%)
Type B1	21	11.31	3.50	Call quality (FER > 2%)
Type C0	27	15.56	4.81	Blocked calls
Type C1	37	22.83	7.06	Call quality (FER > 2%)
Type D0	41	25.78	7.98	Call quality (FER > 3%)
Type D1	41	25.78	7.98	Call quality (FER > 3%)

The results for MUROS-1 show 30-100% gains in Erlang capacity in the cases of TU50 with 65° antenna pattern. With TU3 however, it is not possible to increase voice capacity with MUROS in cases where users have less resilient codecs (AFS 12.2 and AHS 5.9). The performance under the 90° antenna pattern is marginally worse than that achieved with 65° antenna pattern.

6.2.2.2.2 MUROS-2 with 100% penetration

6.2.2.2.2.1 TU 50km/hr channel model

Table 6-10: Simulation results for MUROS-2, TU50 with 65° Antenna

Table 6-13: Simulation results for MUROS-2, TU3 with 90° Antenna

Channel Type	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	86	22.26	12.41	Blocked calls
Type A1	166	45.61	25.43	Call quality (FER > 3%)
Type B0	43	10.09	5.62	Blocked calls
Type B1	69	17.39	9.69	Call quality (FER > 2%)
Type C0	43	10.09	5.62	Blocked calls
Type C1	83	21.39	11.92	Blocked calls
Type D0	86	22.26	12.41	Blocked calls
Type D1	166	45.61	25.43	Call quality (FER > 3%)

In the MUROS-2 configuration with 100% penetration, gains are possible with all codecs and channel types. With TU50, spectral efficiency gains of greater than 100% are possible and the achievable gains are limited by blocked calls in all cases. With TU3, gains as high as 90% are possible. There is little difference in observed results with different antenna patterns.

6.2.2.2.3 MUROS-3A with 100% penetration

6.2.2.2.3.1 TU 50km/hr channel model

Table 6-14 Simulation results for MUROS-3a, TU50 with 65° Antenna

Channel Type	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	64	61.62	13.35	Blocked calls
Type A1	121	125.02	27.09	Call quality (FER > 3%)
Type B0	32	27.35	5.93	Blocked calls

Type D1	40	35.71	7.74	Call quality (FER > 3%)

In MUROS-3a, 60-125% capacity gains are achievable with MUROS for all codecs and channel types with TU 50 channel model. With TU3 capacity gains are observed only in the cases of GSM HR and AFS 5.9. Also worth noting is that MUROS-3a shows the highest achievable spectral efficiency values among all simulated deployment scenarios. This explains why there are cases where all TRX can not be maximally utilized even without MUROS. There are slight differences in performance between 65° and 90° antenna patterns, though the differences are marginal.

6.2.2.2.4 MUROS-3B with 100% penetration

6.2.2.2.4.1 TU 50km/hr channel model

Type D1	36	31.50	6.83	Call quality (FER > 3%)

Table 6-21: Simulation results for MUROS-3b, TU3 with 90° Antenna

Channel Type	Max supportable channels/sector	Spectral Efficiency (Erl/MHz/Site)	Hardware Efficiency (Erl/#TRX)	Limiting Factor
Type A0	55	51.81	11.23	Call quality (FER > 3%)
Type A1	55	51.81	11.23	Call quality (FER > 3%)
Type B0	16	11.31	2.45	Call quality (FER > 2%)
Type B1	16	11.31	2.45	Call quality (FER > 2%)
Type C0	32	27.35	5.93	Blocked calls
Type C1	37	32.60	7.06	Call quality (FER > 2%)
Type D0	33	28.38	6.15	Call quality (FER > 3%)
Type D1	33	28.38	6.15	Call quality (FER > 3%)

With MUROS-3b, modest gains are observed with three of the four codec cases under the TU50 channel model (19 – 125%). With TU3 channel model, however, the capacity gains are seen only in the case of AFS 5.9, depending on the antenna pattern under consideration. The antenna pattern significantly affects performance in MUROS-3b and call quality limitations are observed with lesser numbers of users than in the corresponding cases of MUROS-3a.

6.2.2.2.5 MUROS-2 with less than 100% penetration

In this setup we only consider the 65° antenna pattern with the half rate codecs (GSM HR and AHS 5.9).

6.2.2.2.5.1 TU 3km/hr channel model

Table 6-22 :Simulation results for MUROS-2, TU3 with 65° Antenna: The penetration levels are related to MUROS/DARP/non-DARP receiver type

Channel Type	Penetration (0/70/30) (Erl/MHz/Site)	Penetration (25/50/25) (Erl/MHz/Site)	Penetration (50/35/15) (Erl/MHz/Site)	Penetration (75/17.5/7.5) (Erl/MHz/Site)
Type A0	21.38 (Blocking)	21.38 (Blocking)	21.38 (Blocking)	21.38 (Blocking)
Type A1	21.38 (Blocking)	30.50 (Blocking)	38.27 (Blocking)	41.26 (Blocking)
Type D0	21.38 (Blocking)	21.38 (Blocking)	21.38 (Blocking)	21.38 (Blocking)
Type D1	21.38 (Blocking)	30.50 (Blocking)	37.0 (Call Quality)	41.26 (Blocking)

We see gains in all penetration cases with MUROS because DARP receiver types can be paired with MUROS mobiles without loss of performance. Though the channel allocation algorithm avoids pairing of MUROS mobiles with non-DARP mobiles, the random arrival sometimes lead to large number of non-DARP mobiles. In certain scenarios, the channel allocation algorithm even pairs MUROS mobiles with non-DARP mobiles with good received signal strength.

6.2.2.2.6 Summary

The percentage increases in voice capacity for the different MUROS configurations with different codecs are summarised in the following Tables.

Table 6-23: Summary results with 100% penetration for TU50 with 65° Antenna

Channel Type	MUROS-1	MUROS-2	MUROS-3a	MUROS-3b
Type A	58.4%	104.9%	102.9%	46.6%
Type B	37.1%	112%	65.8%	19.2%
Type C	113.7%	112%	125.3%	125.3%
Type D	8.6%	104.9%	28.6%	1.8%

Table 6-24: Summary results with 100% penetration for TU50 with 90° Antenna

Channel Type	MUROS-1	MUROS-2	MUROS-3a	MUROS-3b
Type A	43.1%	104.9%	90.2%	34.0%
Type B	13.7%	112%	61.8%	7.6%
Type C	113.7%	112%	125.3%	125.3%
Type D	4.3%	104.9%	14.2%	0%

Table 6-25: Summary results with 100% penetration for TU3 with 65° Antenna

Channel type	MUROS-1	MUROS-2	MUROS-3a	MUROS-3b
Type A	23.7%	104.9%	21.4%	0%
Type B	0%	75.1%	0%	0%
Type C	60.8%	112%	69.8%	42.4%
Type D	0%	104.9%	0%	0%

Table 6-26: Summary results with 100% penetration for TU3 with 90° Antenna

Channel type	MUROS-1	MUROS-2	MUROS-3a	MUROS-3b
Type A	10.8%	104.9%	7.1%	0%
Type B	0%	72.3%	0%	0%
Type C	46.7%	112%	61.8%	19.2%
Type D	0%	104.9%	0%	0%

Table 6-27: Summary results with less than 100% penetration: MUROS-2, TU3 with 65° Antenna: The penetration levels are related to MUROS/DARP/non-DARP receiver type

Channel type	25% Penetration (25/52.5/22.5)	50% Penetration (50/35/15)	75% Penetration (75/17.5/7.5)
Type A	42.6%	79%	93.0%
Type D	42.6%	67%	93.0%

In calculation of percentage gains in Table 6-27, the reference receiver ratio is always 0/70/30, though we don"t expect the legacy performance to change with any mix ratio in MUROS-2 deployment scenario, and so the percentage gains will remain same.

6.2.2.3 Performance Summary

Generally, the results for TU-50 channel performance exceed TU-3 performance results for each MUROS configuration and channel mode pair. Significant gains with MUROS are observed in almost all deployment scenarios with TU-50. By comparison, the TU-3 channel lacks short-term time diversity and many users struggle to meet the minimum FER criteria in cases with tight reuse.

We do observe significant MUROS gains even in TU-3 in deployment scenarios which are not inherently interference limited, notably in the low-reuse MUROS-2 configuration. More modest gains are observed in tighter network-planned frequency reuse scenarios such as MUROS-3a, when paired with the AFS 5.9 codec, and to a lesser extent with the GSM HR codec.

MUROS-1 and MUROS-3b are reuse 1:1 deployments, and the system becomes interference limited, especially when less robust codecs (such as AFS 12.2, AHS 5.9) are assigned across all users in the cell. The interference limitations of 1:1 frequency reuse patterns are most acutely seen in the MUROS-3b configurations (which also lack BCCH scheduling). In MUROS-3b, as with MUROS-1, frequency hopping results in interference averaging. However, the antenna patterns used in all configurations do not provide adequate inter-cell interference suppression (maximum of 20 dB from the neighboring cells of same site). The 90° antenna pattern provides worse performance than 65° antenna pattern due to increased inter-cell interference. The DARP receiver provides some interference cancellation but its gains become limited when multiple high interference components are present.

In contrast, the network frequency planning (1:3 reuse) of MUROS-3a provides a measure of intra-site interference avoidance from neighbor cells that the similar MUROS-3b configuration lacks. As a result, for equivalent levels of traffic loading, users across the system suffer significantly in the 1:1 reuse scenarios of MUROS-3b.

We also see that MUROS provides observable benefits when co-existing in deployments with older legacy handsets. For differing levels of MUROS penetration, our results show the general determining factor for system capacity gains remains the channel blocking. The MUROS gains are significant even at lower levels of penetration, with the biggest marginal capacity increase seen between 25% and 50% levels of penetration.

6.2.3 Performance Summary

Two GMSK linear combine and QPSK with 8PSK pulse shaping used for EDGE are similar and keep the spectrum unchanged. They should be the candidate for MUROS DL signal modulation.

MUROS operation needs a few dB margin when compared with current GSM spec points. It is necessary for MUROS operation to work under comparatively better RF condition than normal operation (one caller on one slot) as expected. When the condition of the RF channel become less favorable to MUROS, network should switch the DARP phone back to its normal operation in which the DARP capability can be used for cancelling interference from other cells, as it was intended originally.

Together with the originally intended DARP application, MUROS mode will make better use of DARP capability and enhance the capacity by 100% without changing the traditional frequency planning. Network system level study will be necessary to give in-depth indication of capacity gain under various conditions.

6.3 Impacts on the Mobile Station

The co-TCH concept requires that one of the two mobile stations must support DARP Phase 1. It is not necessary for the two mobiles to support new training sequence codes provided the network assigns a different TSC to each of the two mobile stations and these two training sequence codes are not used by neighbour cells which use the same frequency (ARFCN).

For new mobiles it is desirable to support the new TSC set in addition to the existing TSC set so that network has more flexibility in selecting TSCs. The new TSC set is required to have minimum cross-correlation properties with legacy TSC set. Therefore, it is proposed that MUROS capable mobiles support new TSC set and legacy TSC set. In order to support the use of this new TSC set, Radio Resource signalling changes would be required.

6.4 Impacts on the BSS

6.4.1 Impact on BTS transmitter

For MUROS operation, baseband modulator has to have

1. Abis bandwidth that can carry twice as much as the voice data before MUROS deployment.
2. Two voice channel inputs that can be activated with any of four combinations, i.e.
    a. both user1 and 2 are on (MUROS mode);
    b. both user1 and 2 are off (MUROS mode with both user on DTx);
    c. user1 is on, and user 2 is off (either conventional mode, or user 2 is in DTx); and
    d. user1 is off, and user 2 is on (either conventional mode, or user 1 is in DTx).

If in conventional mode or one user is in DTX mode, then BTS only transmits GMSK for one user only. If both users are in DTx mode, no downlink transmission is needed for this burst.

3. Two different TSCs that are applied to corresponding streams of burst payload when necessary, according to above user 1 and 2 configuration on burst by burst basis.
4. New baseband combining function (could be implemented as FW function).
5. The RF Tx needs linear PA that is capable of handling small percentage of zero crossings. Those BTS that has 8PSK Tx capability would also be suitable.

When both channels are activated, the baseband modulator can take both streams of binary data with two different TSCs applied to corresponding payload streams, and modulate them in such a way that:

1. It satisfies the GMSK mask defined in spec.
2. They are effectively the linear sum of the two independent burst signals that can be well received by legacy mobile stations. For the best channel separation, 90 degrees phase shift between the two independent bursts are needed.

The two signals for each MUROS caller can be of different amplitudes.

6.4.2 Impact on BTS receiver

The receiver needs to be able to decode the two GMSK modulated signals that are separated by a TSC. There are number of BTS receiver techniques that can be employed to provide adequate performance on the uplink, such as duel antenna, joint detection. In general BTS receiver performance is better than MS receiver performance.

6.4.3 Impact on Radio Resource Management

Radio Resource Management (RRM) is considered the most vital component in voice capacity enhancement. RRM has to:

- Determine the most appropriate users to pair together. This may involve the power requirements of each user; the rate of power change; signal quality
- Power control is a crucial part to provide maximum benefit from MUROS mode of operation. Power control can allow users with varying channel conditions to be kept in MUORS mode for longer. Fast power control (i.e. Enhanced Power Control) can be valuable for MUROS mode operation.
- Determine most appropriate point to un-pair users. This has to be a balance between maintaining call quality and spectral efficiency.

In order to support pairing and un-paring of users BSS can use existing procedures to move users from one TCH to another (i.e. intra-cell handover command or assignment command). It is down to BSS implementation which is used.

6.5 Impacts on Network Planning

With increased air interface capacity there would inevitably be a need to increase Abis bandwidth. The Abis bandwidth would need to be dimensioned to support the maximum air interface users. For example, if air interface supports twice as many full rate users then Abis interface would also need to double the bandwidth. The timeline for upgrading Abis to support additional users depends on the deployment of MUROS capable mobiles, as proportion of MUROS capable mobiles increase, the Abis bandwidth would need to be increased accordingly.

6.6 Impacts on the Specification

The impact on specifications is shown in Table 6-28 below.

Table 6-28: Impact on specification with co-TCH

3GPP Specification	Impact
TS 44.018 – RR signalling	Signalling changes to support new TSC for use with CS connections.
TS 24.008	Signalling changes for MS to indicate support for new TSC set.
TS 45.002	Define new TSC set.
TS 45.004	Define new modulation scheme for downlink.
TS 45.005	Define performance requirements for MUROS type modulation.
TS 51.010	Define new performance and signalling tests cases for MUROS capable mobiles.

6.7 Summary of Evaluation versus Objectives

In this section the candidate technique is evaluated against the defined objectives in chapter 4. Note, this section represents the view of the proponents of this candidate technique.

The following classification is used for the evaluation:

Fulfilled

Expected to be fulfilled

Unclear/FFS

Not fulfilled

6.7.1 Performance objectives

Performance Objectives	Candidate Technique: Co-TCH
P1: Capacity Improvements at the BTS 1) increase voice capacity of GERAN in order of a factor of two per BTS transceiver 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Gains have been shown to be between 0 and 125 % depending on the system scenario and speech codec.
	2) All voice codecs are supported
P2: Capacity Improvements at the air interface 1) enhance the voice capacity of GERAN by means of multiplexing at least two users simultaneously on the same radio resource both in downlink and in uplink 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Two users are multiplexed on the same radio resources
	2) All speech codecs are supported

6.7.2 Compatibility objectives

Compatibility Objectives	Candidate Technique: Co-TCH

C1: Maintainance of Voice Quality 1) voice quality should not decrease as perceived by the user. 2) A voice quality level better than for GSM HR should be ensured.	1) Only users with good RF conditions will be allocated on a channel supporting co-TCH. Simulations have shown that there are no losses in user satisfaction, only gains, when using the new technique.
	2) Both AMR and GSM HR codecs have been investigated. Given the same RF condition, the voice quality of ARM codecs is better than GSM HR.
C2: Support of Legacy Mobile Stations 1) Support of legacy MS w/o implementation impact. 2) First priority on support of legacy DARP phase 1 terminals, second priority on support of legacy GMSK terminals not supporting DARP phase 1.	1) Legacy, DARP Phase I, mobiles can be supported. Downlink power control will support legacy mobiles.
	2) Legacy DARP Phase I terminals will be supported. Non DARP Phase I terminals have been shown to support the concept on link level. System level studies are still needed to show the gains with non DARP mobile stations.
C3: Implementation Impacts to new MS's 1) change MS hardware as little as possible. 2) Additional complexity in terms of processing power and memory should be kept to a minimum.	1) Minimum requirement is to support new training sequences. Impact of new training sequences on complexity and memory requirements is minimal.
	2) More advanced receiver implementations, such as joint detection, can improve performance and this will have impact on complexity and memory.
C4: Implementation Impacts to BSS 1) Change BSS hardware as little as possible and HW upgrades to the BSS should be avoided. 2) Any TRX hardware capable for MUROS shall support legacy non-SAIC mobiles and SAIC mobiles. 3) Impacts to dimensioning of resources on Abis interface shall be minimised.	1) Demodulation of two simultaneous signals, support of new training sequences and linear modulator.
	2) The concept has no impact on TRX to support different type of mobiles.
	3) The Abis interface capacity needs to be increased in accordance with the increased number of channels supported by MUROS.
C5: Impacts to Network Planning 1) Impacts to network planning and frequency reuse shall be minimised. 2) Impacts to legacy MS interfered on downlink by the MUROS candidate technique should be avoided in case of usage of a wider transmit pulse shape on downlink. 3) Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator"s band allocation and in country border regions where no frequency coordination are in place.	1) No impact on frequency planning or frequency re-use is foreseen.
	2) A wide pulse shape has only been investigated on link level. System level simulations are needed to investigate the impact of a wider pulse. This proposal does not prevent use of wide pulse.
	3) If a wide pulse shape is to be deployed it is not expected to be used at the edge of an operator"s frequency band.

7 Orthogonal Sub Channels for Circuit Switched Voice Capacity Evolution

7.1 Concept description

7.1.1 Overview

A new study item MUROS [7-1] was agreed at GERAN#36 aiming to improve voice efficiency. In this section the orthogonal sub channel (OSC) [7-2] concept is presented. It multiplexes two MSs simultaneously allocated on the same radio resource. OSC is applicable for low end handsets, since the concept is relying on GMSK capability of handsets. Sub channels are separated by using non-correlated training sequences. OSC can considerably increase voice capacity with low impact to handsets as well as to networks. The concept may provide e.g. a double half rate channel providing that 4 users can be allocated to the same radio slot.

The orthogonal sub channel concept in downlink is based on QPSK like modulation, where each of the sub channels is mapped so that it can be received as GMSK signal.

In uplink direction, mobiles allocated to the orthogonal sub channels may use the genuine GMSK modulation with different training sequences. Both orthogonal sub channels are simultaneously received by the BTS that needs to employ e.g. diversity and interference cancellation means to separate the orthogonal sub channels.

In general, the OSC concept relying on GMSK only handsets can offer up to double voice capacity.

The orthogonal sub channel concept by nature doubles the number of channels. One of the key changes is the introduction of new training sequences paired with existing training sequences for lowest cross-correlation to enable separation of sub channels. The first sub channel can use an existing training sequence serving a legacy MS, whilst the second sub channel should preferably use a new training sequence for both downlink and uplink.

OSC can be applied e.g. for TCH/F, TCH/H and related associated control channels (FACCH and SACCH) making it as transparent as possible to deploy it for all GMSK modulated traffic channels.

7.1.2 Downlink concept

The downlink concept is depicted in this section. It is splitted into a basic concept and into an enhanced concept.

7.1.2.1 Basic OSC concept

7.1.2.1.1 Mapping of user bits using QPSK modulation

The Basic OSC concept is characterized in downlink in that BTS transmitter uses QPSK type of constellation that may be e.g. a subset of 8PSK constellation used for EGPRS. Modulating bits are mapped to QPSK symbols i.e. 'dibits' e.g. so that the first sub channel (OSC-0) is mapped to MSB and the second sub channel (OSC-1) is mapped to LSB as illustrated below.

An example of mapping bits to QPSK like constellation based on 8PSK modulator is shown in Table 7-1 and Figure 7-1. Both sub channels are mapped to QPSK symbol orthogonally.

Table 7-1: Mapping between OSC modulating bits and the 8PSK symbol parameter *I*

Original Gray mapped 8PSK Modulating bits d_{3i}, d_{3i+1}, d_{3i+2}	Mapping of bits for orthogonal sub channels to 8PSK symbols OSC_0, OSC_1	Symbol parameter *I* for rule $s_i = e^{j2\pi I/8}$
(1,1,1)	-	0
(0,1,1)	(1,1)	1
(0,1,0)	-	2
(0,0,0)	(0,1)	3
(0,0,1)	-	4
(1,0,1)	(0,0)	5
(1,0,0)	-	6
(1,1,0)	(1,0)	7

This is illustrated in Figure 7-1.

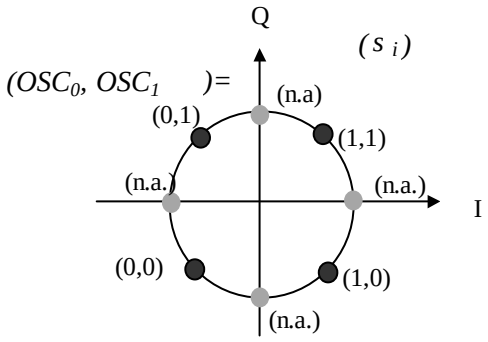

Figure 7-1: Mapping of OSC modulating bits into 8PSK symbols.

Both sub channels may use individual ciphering e.g. A5/1 or A5/3. The symbol rotation of π/2 used in downlink allows multiplexing with legacy handsets and enables also to use GMSK in case of DTX and FACCH / SACCH signalling, see sections 7.1.2.1.5, 7.1.2.1.6 and 7.1.2.1.7.

7.1.2.1.2 Burst structure, training sequence, tail and guard bits

The burst structure should be compatible with the existing bursts. Existing GMSK tail bits and guard bits could be applied for both sub channels separately. The set of new training sequences dedicated to the second sub channel are paired with current training sequences for the lowest cross-correlation with optimal autocorrelation and are listed in Table 7-2. The training sequences have been obtained by performing a full LS channel estimation based cumputational search [7-2].

Table 7-2: Set of new training sequences (TSCs) paired with current one

Training sequence code	Training sequence bits
0	0 0 1 0 1 1 0 1 1 1 0 1 1 1 0 1 0 0 0 1 1 1 1 0 1 1
1	0 0 0 1 0 0 0 1 1 1 1 0 1 0 0 1 0 0 1 0 0 0 1 0 0 0
2	0 1 1 1 0 1 0 0 1 0 0 0 0 1 0 0 0 1 0 0 0 1 1 1 1 0
3	0 1 0 0 0 1 0 0 0 1 1 1 0 0 0 0 1 0 1 1 0 1 1 1 0 1
4	0 1 0 0 0 1 0 1 1 0 0 0 0 1 0 1 1 0 0 0 1 0 0 0 0 0
5	0 1 0 1 1 1 1 1 0 0 1 0 0 1 1 1 0 0 1 0 1 0 0 0 0 0
6	0 1 1 1 0 1 1 1 1 0 0 1 0 1 1 1 1 0 0 1 0 0 0 1 0 1
7	0 0 1 0 1 0 1 1 0 0 1 1 1 1 1 1 0 0 1 1 1 1 0 1 0 1

Figure 7-2 below illustrates cross correlation properties between existing and new training sequences. It can be seen that new training sequences have better cross correlation property in general with all existing training sequences, not only with its pair.

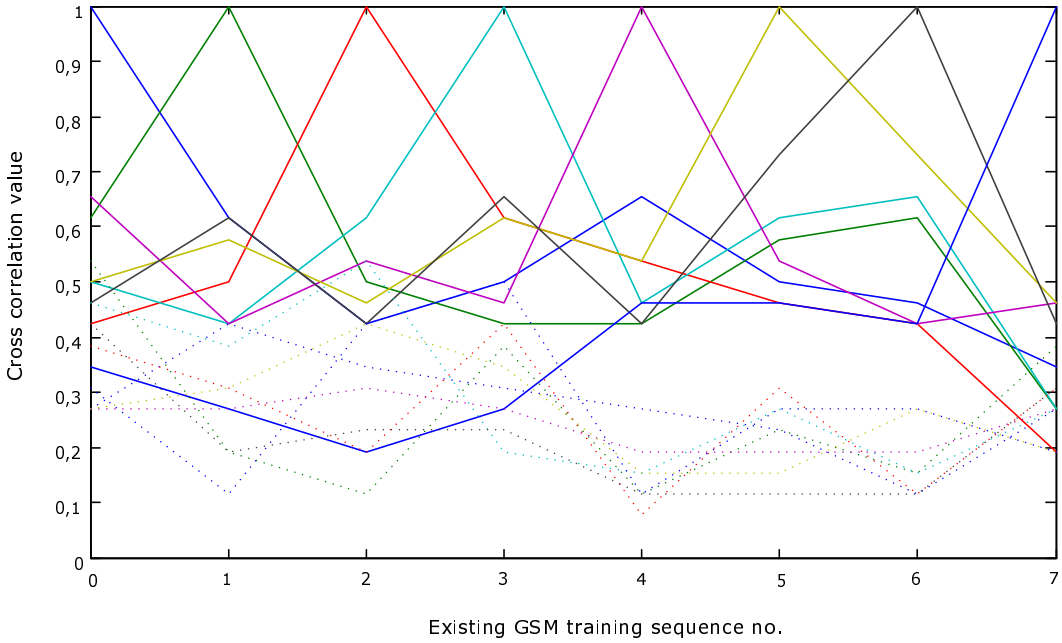

Figure 7-2 Illustration of Cross correlation properties between existing training sequences (solid line) and between new and existing training sequences (dotted line).

7.1.2.1.3 Tx pulse shaping filter

Different Tx pulse shaping filters were used in DL simulations such as Hanning windowed Root Raised Cosine with roll-off 0.3 and bandwidth equivalent to symbol rate (270 kHz) and the current linearised GMSK pulse. In addition it is worth to consider further optimisation of the Tx pulse shape with different criteria e.g. system performance and MS receiver performance. Performance characterization for above Tx pulse shapes can be found in section 7.2.1.1.1.

7.1.2.1.4 Symbol rotation

For symbol rotation the compatibility with GMSK makes rotation of $\pi/2$ the best choice. Thus with above specified RRC filter the peak to average ratio (PAR) is only 2.2 dB, whilst being 3.4 dB for linearised GMSK pulse.

7.1.2.1.5 DTX handling when one sub channel is inactive

When the paired sub channel is inactive due to DTX, it is possible to send normal GMSK bursts instead of QPSK for the active sub channel using the training sequence of the active sub channel. The transmit power can be reduced during that period of time. The change of modulation applies after sending the last burst of the SID_FIRST message or of the SID_UPDATE message, respectively, on the paired sub channel. Similarily, the change from GMSK to QPSK applies when the first burst of the SID_UPDATE or ON_SET message, respectively, needs to be sent on the paired sub channel. In system point of view this OSC scheme has a different behaviour in DTX mode in downlink. Combined transmitter activity will be higher than for single user, but on the other hand two users are served simultaneously.

7.1.2.1.6 FACCH signalling

Different options exist for transmission of FACCH for orthogonal sub channels in downlink:

- First option is to straightforward apply the FACCH signalling as for legacy channels, but mapped to the sub channels.

- Second option is to steal voice payload bursts from both OSC sub channels to make signalling more robust e.g. for speeding up intra cell handovers. In this case the training sequence of the sub channel, transporting the GMSK modulated FACCH, is being used for discrimination.

- Third option is to employ Repeated DL FACCH per sub channel, which has been standardised for full rate and half rate channels in GERAN Rel-6.

- Fourth option is to use Soft Stealing for FACCH employing sub channel specific power control (see section 7.1.2.2.3).

Performance comparision between all three proposals is FFS.

7.1.2.1.7 SACCH signalling

SACCH performance for OSC full rate traffic channels and OSC half rate channels needs to be designed such that RR signalling carried on downlink gets sufficiently robust.

In case of OSC full rate channels different options exist in downlink:

- First option is to straightforward apply the SACCH signalling as for legacy channels, but mapped to the subchannels. Hence the SACCH blocks of both subchannels are simultaneously transmitted.

- Second option is the usage of Repeated SACCH as standardized in GERAN Rel-7 for full rate traffic channels. This option is suited if legacy mobiles supporting Repeated SACCH are multiplexed on both sub channels, but also in case new OSC aware mobiles are multiplexed or for a mix of legacy mobiles supporting Repeated SACCH and OSC aware mobiles.

- Third option is to shift the SACCH transmission for new OSC aware mobiles by 13 TDMA frames to the curent idle frames. Hence new OSC aware mobiles use the SACCH allocation related to the second channel in a half slot channel configuration. This is depicted in section 7.1.2.2.5.3 for the Optimized User Diversity Full Rate Pattern 1. Hence using GMSK modulated bursts for SACCH/F the same perfomance as for legacy mobiles is achieved.

In case of OSC half rate channels different options exist for SACCH in downlink:

- First option is to straightforward apply the SACCH signalling as for legacy channels, but mapped to the sub channels. Hence the SACCH blocks of both sub channels are simultaneously transmitted.

- Second option is the usage of Repeated SACCH as standardized in GERAN Rel-7 for half rate traffic channels. This option is suited if legacy mobiles supporting Repeated SACCH are multiplexed on both sub channels, but also in case new OSC aware mobiles are multiplexed or for a mix of legacy mobiles supporting Repeated SACCH and OSC aware mobiles.

- Third option is to use Soft Stealing for SACCH with sub channel specific power control and user diversity (see section 7.1.2.2.4). This option does only exist if at least one OSC aware mobile is multiplexed.

Performance comparision between all three above proposals is FFS.

7.1.2.2 Enhanced OSC concept

The Enhanced OSC concept is based on three techniques which complement the Basic OSC concept and thus increase the performance benefits of OSC in that the interworking to legacy mobiles is improved and increased network capacity is achieved.

7.1.2.2.1 Sub channel specific power control

As proposed in [7-3] power control in downlink needs to be performed commonly for both sub channels i.e. based on the highest power demand of two users. Two individual radio path losses or receiver performances may not always be balanced, thus sub channel specific power control needs to be addressed. The enhancement is related to a sub channel specific power control mechanism based on non-square, but rectangular 4QAM constellation provided by 8PSK constellation. The sub channel specific power control utilises normal 8PSK constellation with rotation changed to $\pi/2$. Power levels can be adjusted by changing the mapping of users in that different subsets of 4QAM symbols are selected out of the 8PSK constellation diagram as depicted in Figure 7-3.

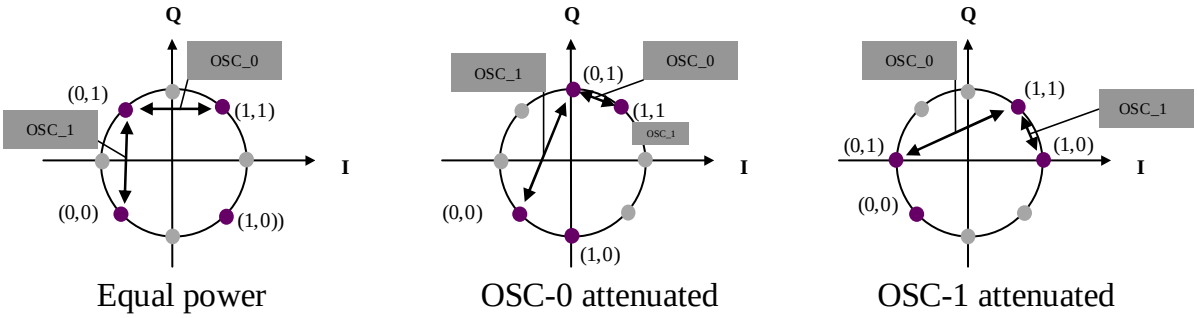

Figure 7-3: Mapping of OSC sub channels with equal or unequal sub channel powers

The OSC sub channel with higher power may experience about 2.3 dB higher power than with equal power OSC and the OSC sub channel with lower power about 5.3 dB lower power, compared to the equal power case, whilst the difference between higher and lower power is 7.7dB. By alternating between 3 different levels from burst to burst it is possible to achieve effectively several level values in within 7.7 dB range. The mapping of encoded bits of both subchannel onto 8PSK constellation points for subchannel specific power control is specified in Table 7-3.

Table 7-3: Mapping between OSC modulating bits and the 8PSK symbol parameter *l*.

Original Gray mapped 8PSK Modulating bits d_{3i}, d_{3i+1}, d_{3i+2}	**Symbol parameter *l* for rule $s_i = e^{j2\pi l/8}$**	**Mapping of bits for orthogonal sub channels to 8PSK symbols OSC_0, OSC_1**		
		Signal powers: $OSC_0 = OSC_1$	**Signal powers: $OSC_0 > OSC_1$**	**Signal powers: $OSC_0 < OSC_1$**
(1,1,1)	0	-	(0,1)	-
(0,1,1)	1	(1,1)	(1,1)	(1,1)
(0,1,0)	2	-	-	(0,1)
(0,0,0)	3	(0,1)	-	-
(0,0,1)	4	-	(1,0)	-
(1,0,1)	5	(0,0)	(0,0)	(0,0)
(1,0,0)	6	-	-	(0,1)
(1,1,0)	7	(1,0)	-	-

The SAIC handset is expected to cancel part of the interference power caused by OSC when applying sub channel specific power control as depicted in Figure 7-4.

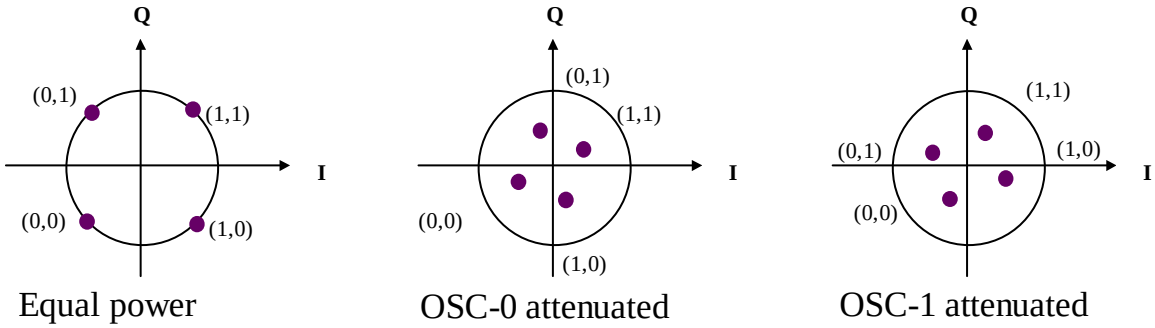

Figure 7-4: Illustration of OSC signals after SAIC processing by MS in neighbour cell

Thus SAIC gains could be likely obtained with sub channel specific power control. Performance is characterized in sections 7.2.1.1.1.2 and 7.2.1.2.1.2.

In summary sub channel specific power control is considered beneficial due to several reasons:

- Equal power is not optimal for both OSC sub channels under all radio conditions
- SAIC may be able to successfully cancel part of such an attenuated interference coming from the subchannel user
- FACCH and SACCH may be boosted by a couple of dB without muting possible voice on other sub channel (see section 7.1.2.2.3 and 7.1.2.2.4).

7.1.2.2.2 Power Balancing

Power Balancing is an extension of the sub channel specific power control mechanism, in that the selected constellation as depicted in Figure 7-3 and Table 7-3 is modified from burst to burst. Hence the sub channel specific power can be balanced with a higher resolution between both sub channels using different patterns. An examplary pattern is depicted in Table 7-4. The pattern is selected by the BTS depending on the reported link measurements for both sub channels.

Table 7-4: Usage of different OSC constellations for power balancing (example).

TDMA frame mod 8	OSC Constellation
0	Equal Power
1	OSC-0 attenuated
2	OSC-0 attenuated
3	Equal Power
4	Equal Power
5	Equal Power
6	OSC-0 attenuated
7	OSC-0 attenuated

7.1.2.2.3 Soft Stealing for FACCH with sub channel specific power control

Sub channel specific power control can be applied when an FACCH needs to be sent on downlink. In this case the FACCH block for the sub channel of interest is carried on the stronger channel. This may improve FACCH, compared to the case of equal power and improves robustness of RR signalling without performing 'double stealing' of voice blocks from both sub channels (see section 7.1.2.1.6.).

7.1.2.2.4 Soft Stealing for SACCH with sub channel specific power control

Sub channel specific power control can also be applied for OSC half rate channel when a SACCH needs to be sent on downlink and a TCH channel is active for the paired user. This is proposed in section 7.1.2.2.5.3 for Optimized User Diversity Half Rate Pattern 3. Likewise as for FACCH the SACCH block for the sub channel of interest is carried on the stronger channel and hence robustness of RR signalling (i.e. SYSTEM INFORMATION and MEASUREMENT INFORMATION messages as well as UL power control commands) is improved.

7.1.2.2.5 User Diversity

In order to fully exploit gains of DTX with OSC, this enhancement of the basic OSC concept presented in [7-4] and refined in [7-5] introduces a multiplexing scheme where either 4 users on two HR channels or 4 users on two FR channels are mixed together to increase variance on number of simultaneous active users over an interleaving period. Increased variance is intended to provide better conditions for channel coding to operate. The concept is suited both for downlink and for uplink.

7.1.2.2.5.1 Basic User Diversity

With OSC HR or OSC FR, respectively, and with DTX enabled, bursts are carrying either no, one or two users without any or with low variance on number of simultaneous users over the interleaving period. This can be considered sub-optimal from channel coding point of view. To improve this variance over the interleaving period, 4 users in two HR channels on one timeslot or 4 users in two FR channels on a timeslot pair can be mixed so that $\binom{4}{2} = 6$ possible pairing combinations are evenly used changing frame by frame. This kind of multiplexing exploiting the diversity related to the activity status of each of the 4 users is named ***Basic User Diversity*** here and is expected to improve the

radio performance in both downlink and uplink. Note this feature assumes that the channels carry DTX"ed speech. If DTX is not activated the feature will not yield performance benefits.

One possible way to define the mixing of OSC HR users with DTX activated is given in Table 7-5 below and is based on the specification of a ***user diversity pattern***, which is specific for each user and which defines the way how a burst of each frame is mapped to an OSC sub channel and in case of a half rate channel to the (HR) sub channel of a slot. User diversity patterns should be defined so that users are evenly multiplexed with each other users. That pattern may be built with two bits per frame, where the first bit indicates the OSC sub channel and the second bit indicates the used (HR) sub channel. Table 7-5 illustrates how the user diversity pattern could be applied over 12 TDMA frames. The used training sequence may be linked with the OSC sub channel, thus 2 training sequences are shared with 4 users changing according to OSC sub channel.

Table 7-5: Examplary 'user diversity pattern' to mix 4 OSC HR users [7-4]

Frame	Active HR SC	User Diversity Pattern (OSC, SC)				User in OSC	
		User 1	User 2	User 3	User 4	OSC-0	OSC-1
0	**0**	00	01	11	10	User 1	User 4
1	**1**	10	11	00	01	User 4	User 2
2	**0**	01	10	11	00	User 4	User 2
3	**1**	11	00	01	10	User 3	User 1
4	**0**	00	11	10	01	User 1	User 3
5	**1**	10	01	11	00	User 2	User 3
6	**0**	00	01	11	10	User 1	User 4
7	**1**	10	11	00	01	User 4	User 2
8	**0**	01	10	11	00	User 4	User 2
9	**1**	11	00	01	10	User 3	User 1
10	**0**	00	11	10	01	User 1	User 3
11	**1**	10	01	11	00	User 2	User 3

active user transmission in TDMA frame
time instant related to delivery of speech block

The table could also be extended to differentiate on SACCH and TCH bursts. It might be possible to distribute start of TCH interleaving periods of each user evenly e.g. with offset of one frame. That might be beneficial by offering even distribution of processing load e.g. in channel decoder of BTS. Indeed SACCH bursts could be evenly distributed to provide DTX gains due to mixing also to SACCH performance. If user diversity pattern with length of 12 is repeated periodically it would allow SACCH bursts located every 120ms for the same user.

However, as shown above, the user diversity pattern leads to a irregular delivery of speech blocks for users 1 to 4 taking into account the speech block delivery every other burst in case of HR channel. For example, as can be seen in Table 7-5, for user 1 the speech block is delivered in Frame 3, Frame 6, Frame 10 and Frame 12+3=15, hence the delivery of the speech block experiences a delay between 3 frames and 5 frames and yields a jitter of about ± 5 ms. This is undesirable considering speech latency performance. The same jitter is present for user 2 whilst user 3 to 4 experience an even higher change of delay between 2 and 5 frames, hence about ± 7.5 ms.

Thus the *Basic User Diversity* concept as proposed in [7-4] has following drawbacks:

1) This kind of statistical multiplexing is based on the assumption that the mobiles know when to transmit and receive in a given TDMA frame and which OSC training sequence to use. Consequently one drawback is that the proposed scheme in [7-4] cannot be applied to legacy mobiles in the field. In other words legacy mobiles operated in OSC channels cannot benefit in terms of reduced interference.

2) A second drawback is that the scheme introduces a jitter due to the variable block lengths as shown in Table 7-5 and described above. An additional jitter in the order of ± 5 ms or even ± 7.5 ms is introduced which may need some adaptation of network interfaces and identifies an add-on to peak delays for speech.

3) Also the concept was merely investigating the OSC half rate case and provided increased interference diversity in one timeslot, whilst it was not considering the OSC full rate case.

7.1.2.2.5.2 Optimized User Diversity

In this section modifications to the *Basic User Diversity* procedure as decribed in [7-4] are presented in order to mitigate the above mentioned drawbacks. In particular, the described modifications detailed hereafter allow to multiplex legacy mobiles with new OSC aware mobiles in order to let all mobiles benefit from interference diversity and hence mitigates the conceptual drawbacks of the original proposal as sketched in the section above. The ***Optimized User***

Diversity concept also introduces a constant speech delay for each user, avoiding any jitter. Moreover it considers the issue of increasing interference diversity for a full rate channel configuration and is based on the assumption that DTX is in use both for DL and UL operation.

Since OSC is not expected to operate in tight reuse scenarios with high level of external interference, the main interferer in most situations stems from the paired sub channel. Taking into account that DTX is activated, interference diversity can be improved if different users are multiplexed on the paired sub channel. In case of inactivity of either of both sub channels in downlink the BTS can make use of GMSK rather than QPSK and hence transmission can be operated with lower power backoff. In UL reduction of GMSK modulated interference is beneficial in interference limited scenarios and thus will reduce transmit power of mobiles and also increase network capacity.

The enhancements described below are related to the definition of a set of *optimized user diversity* patterns for both OSC half rate and OSC full rate channel configurations. The patterns are optimised for a given mix of mobiles. In order to adapt to the actual mix of mobiles, e.g. share of legacy mobiles and share of new OSC aware mobiles, it is proposed to enable switching between these patterns for OSC half rate channel configuration and for OSC full rate channel configuration, respectively. It has to be noted that the proposed user diversity patterns for enhanced OSC are fixed patterns and not changing in time. Hence it is sufficient to signal the pattern at channel assignment or after channel mode adaptation to the mobile of interest.

For OSC half rate channel configuration legacy mobiles can be included with their legacy transmission behaviour based on the interleaving depth 4 and time diversity of 35 ms. For new OSC aware mobiles the same interleaving depth 4 is selected leading to a time diversity of 30 ms (optimized user diversity half rate pattern 2 and 3).

In addition for OSC half rate channel configuration the SACCH of the second sub channel is advanced by 6 TDMA frames compared to the first sub channel to achieve also interference diversity for this channel (optimized user diversity half rate pattern 3), assuming that the paired sub channel carries DTX"ed speech. The enhancements include also the extension of the user diversity algorithm to paired timeslots as depicted in Figure 7-5.

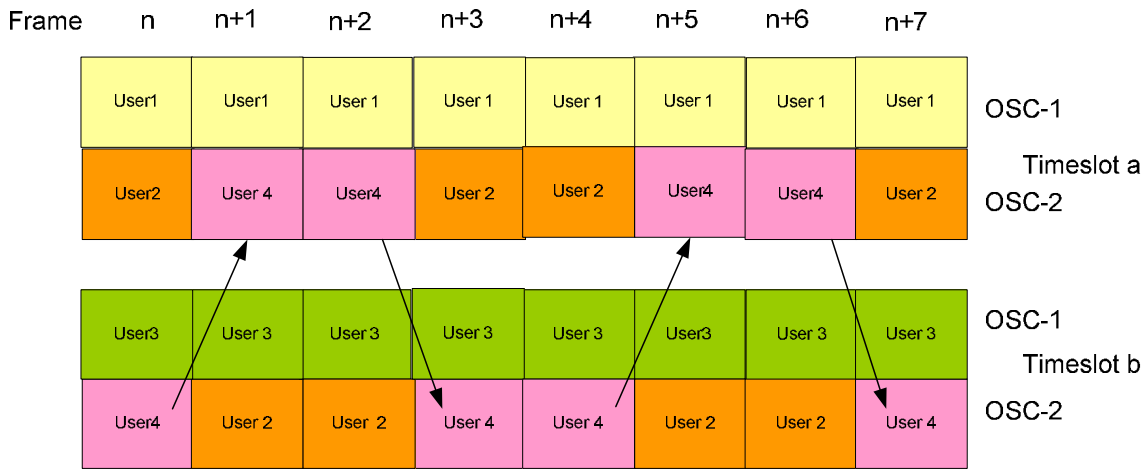

Figure 7-5: Optimized User Diversity for OSC full rate channel configuration for the case of a timeslot pair

Interference diversity is achieved here by multiplexing two full rate OSC aware mobiles (User 2 and User 4) on a paired timeslot (timeslot b) to the second sub channel (OSC-2) of the first timeslot (timeslot a).

The concept foresees to allocate two legacy full rate mobiles (User 1 and User 3) on the first sub channel (OSC-1) of the timeslot pair (timeslot a and b), where the time slots need not be adjacent. The remaining OSC aware MS"s (User 2 and User 4) are then mandated to hop between the second sub channels (OSC-2) of both timeslots. In case of OSC full rate channel configuration the interleaving depth of 8 is kept for all mobiles, also time diversity of ~ 40 ms is maintained for all mobiles without jitter. As well speech block delivery every 4th burst is untouched.

Hence in all cases legacy MS"s and new OSC aware mobiles will benefit from the increased interference diversity through the usage of legacy compatible user diversity patterns. The patterns are described in section 7.1.2.2.5.3 . It is

intended that the specified *optimized user diversity* patterns are subject to be standardized. intra cell or channel modify HO command, etc.

Signalling support for OSC aware mobiles will then include:

- the specified user diversity pattern (2 bits in case of OSC FR channel configuration and 2 bits in case of OSC HR channel configuration).
- the index for the mobile (2 bits for multiplexing 4 users).
- signalling will be needed if user patterns are switched.
- different signalling methods exist: usage of FACCH to command an intracell HO, usage of inband signalling to transport compressed

7.1.2.2.5.3 Support of Optimized User Diversity for scenarios with mixed MS types

For OSC half rate channel configuration and OSC full rate channel configuration three user diversity patterns for each are defined for each to support inclusion of legacy MSs. Half rate configuration is always related to one time slot, whilst full rate configuration is based on two timeslots in two of three configurations in order to obtain a higher interference diversity.

Optimized User Diversity Half Rate Pattern 1

The channel configuration depicted in Table 7-6 is related to one timeslot. The configuration supports of up to four users for the following two scenarios:

a) 4 legacy MS"s.

b) 3 legacy MS"s + 1 OSC aware MS.

Table 7-6: Optimized User Diversity Half Rate Pattern 1 per 26 multiframe

Frame	Active	User Diversity Pattern (OSC, SC)				User in OSC	
	HR SC	User 1	User 2	User 3	User 4	OSC-0	OSC-1
0	**0**	00	10	01	11	User 1, Bx+B0	User 2, Bx+B0
1	**1**	00	10	01	11	User 3, Bx+B0	User 4, Bx+B0
2	**0**	00	10	01	11	User 1, Bx+B0	User 2, Bx+B0
3	**1**	00	10	01	11	User 3, Bx+B0	User 4, Bx+B0
4	**0**	00	10	01	11	User 1, B0+B1	User 2, B0+B1

c) User 1 to User 4: legacy MS or legacy SAIC MS.

d) User 1 to User 3: legacy MS or legacy SAIC MS; User 4: OSC aware MS (one example).

Optimized User Diversity Half Rate Pattern 2

The channel configuration depicted in Table 7-7 is related to one timeslot. The configuration supports up to four users for the following three scenarios:

a) 2 legacy MS"s + 2 OSC aware MS"s.

b) 1 legacy MS"s + 3 OSC aware MS"s.

c) 4 OSC aware MS"s.

Table 7-7: Optimized User Diversity Half Rate Pattern 2 per 26 multiframe

Frame	Active	User Diversity Pattern (OSC, SC)				User in OSC	
	HR SC	User 1	User 2	User 3	User 4	OSC-0	OSC-1
0	**0**	00	10	01	11	User 1, Bx+B0	User 2, Bx+B0
1	**1**	00	11	01	10	User 3, Bx+B0	User 2, Bx+B0
2	**0**	00	11	01	10	User 1, Bx+B0	User 4, Bx+B0

24	**1**	00	10	01	11	User 3, B4+B5	User 4, B4+B5
25	**1**	00	10	10	11	**User 3, SACCH**	**User 4, SACCH**

a) User 1 and User 3: legacy MS or legacy SAIC MS; User 2 and User 4: OSC aware MS"s.

b) User 1: legacy MS or legacy SAIC MS; User 2 to User 4: OSC aware MS"s.

c) User 1 to User 4: OSC aware MS"s.

Optimized User Diversity Half Rate Pattern 3

The channel configuration depicted in Table 7-8 is related to one timeslot. The configuration supports the same scenarios as Pattern 2 and up to four users for the following three scenarios:

a) 2 legacy MS"s + 2 OSC aware MS"s.

b) 1 legacy MS"s + 3 OSC aware MS"s.

c) 4 OSC aware MS"s.

Table 7-8: Optimized User Diversity Half Rate Pattern 3 with shift of SACCH per 26 multiframe

Frame	Active	User Diversity Pattern (OSC, SC)				User in OSC	
	HR SC	User 1	User 2	User 3	User 4	OSC-0	OSC-1
0	**0**	00	10	01	10	User 1, Bx+B0	User 2, Bx+B0

24	**1**	00	10	01	11	User 3, B4+B5	User 4, B4+B5
25	**1**	00	10	01	11	**User 3, SACCH**	User 4, B4+B5

a) User 1 and User 3: legacy MS or legacy SAIC MS; User 2 and User 4: OSC aware MS"s.

b) User 1: legacy MS or legacy SAIC MS; User 2 to User 4: OSC aware MS"s.

c) User 1 to User 4: OSC aware MS"s.

Note the difference to Pattern 2 is the shift of the SACCH for User 2 and User 4 , i.e. the advance of 6 TDMA frames.

Optimized User Diversity Full Rate Pattern 1

The channel configuration depicted in Table 7-9 is related to one timeslot. The configuration supports up to two users for the following three scenarios:

a) 2 legacy MS"s.

b) 1 legacy MS"s + 1 OSC aware MS.

c) 2 OSC aware MS.

Table 7-9:Optimized User Diversity Full Rate Pattern 1 per 26 multiframe

7	1	**1**	00	10	01	11	User 3, B0+B1	User 4, B0+B1
8	0	**0**	00	10	01	11	User 1, B1+B2	User 2, B1+B2
8	1	**1**	00	10	01	11	User 3, B1+B2	User 4, B1+B2
9	0	**0**	00	10	01	11	User 1, B1+B2	User 2, B1+B2
9	1	**1**	00	10	01	11	User 3, B1+B2	User 4, B1+B2
10	0	**0**	00	10	01	11	User 1, B1+B2	User 2, B1+B2
10	1	**1**	00	10	01	11	User 3, B1+B2	User 4, B1+B2
11	0	**0**	00	10	01	11	User 1, B1+B2	User 2, B1+B2
11	1	**1**	00	10	01	11	User 3, B1+B2	User 4, B1+B2
12	0	**0**	00	10	01	11	**User 1, SACCH**	**Legacy User 2, SACCH**
12	1	**1**	00	10	01	11	**User 3, SACCH**	**Legacy User 4, SACCH**
13	0	**0**	00	10	01	11	User 1, B2+B3	User 2, B2+B3
13	1	**1**	00	10	01	11	User 3, B2+B3	User 4, B2+B3
14	0	**0**	00	10	01	11	User 1, B2+B3	User 2, B2+B3
14	1	**1**	00	10	01	11	User 3, B2+B3	User 4, B2+B3
…								
25	0	**0**	00	10	01	11	-	
25	1	**1**	00	10	01	11	-	**OSC User 4, SACCH**

a) User 1 to User 4: legacy MS or legacy SAIC MS; all users use Frame 12 for SACCH.

b) User 1 to User 3: legacy MS or legacy SAIC MS; User 4: OSC aware MS (one example); User 4 uses SACCH in Frame 25. Hence the OSC aware user uses Frame 25 for SACCH in this configuration. Instead of User 4, User 2 could identify an OSC aware MS. In this case the SACCH for OSC User 2 is allocated in Frame 25 TS 0.

Optimized User Diversity Full Rate Pattern 3

The channel configuration depicted in Table 7-11 is related to a timeslot pair. The configuration supports up to four users for the following three scenarios:

a) 2 legacy MS"s + 2 OSC aware MS"s.

b) 1 legacy MS"s + 3 OSC aware MS"s.

c) 4 OSC aware MS"s.

Table 7-11: Optimized User Diversity Full Rate Pattern 3 per 26 multiframe

Frame	TS	Active	User Diversity Pattern (OSC, SFS)				User in OSC	
		SFS	User 1	User 2	User 3	User 4	OSC-0	OSC-1

14	1	**1**	00	11	01	10	User 3, B2+B3	User 2, B2+B3
…								
25	0	**0**	00	10	01	11	-	**User 2, SACCH**
25	1	**1**	00	10	01	11	-	**User 4, SACCH**

a) User 1 and User 3: legacy MS or legacy SAIC MS; User 2 and User 4: OSC aware MS"s.

b) User 1: legacy MS or legacy SAIC MS; User 2 to User 4: OSC aware MS"s.

c) User 1 to User 4: OSC aware MS"s.

7.1.2.2.5.4 Benefits of Optimized User Diversity

Optimized User Diversity will mitigate the drawbacks of the Basic User Diversity proposal in the context of impact of variable speech block delivery and of coexistence scenarios with legacy mobiles. Different patterns for full rate and half rate channells have been designed in such way

- that they allow to apply the same constant interleaving depth for full rate channels (8 bursts) as for legacy channels,
- that they allow to apply the same constant interleaving depth for half rate channels (4 bursts) as for legacy channels and an reduced transfer delay by 5ms (30 ms instead of 35 ms) and
- that they can serve a variable mix of legacy and new OSC aware mobiles with least signalling. In particular signalling support for new OSC aware mobiles will be needed to index the user diversity pattern and the position of the user, hence a total of 4 bits per user. The method for this signalling support is FFS.

As outlined in [7-4] the proposed method will yield increased interference diversity both for TCH and SACCH channels in OSC configurations and is independent of employed frequency hopping type. Hence no frequency planning aspects are imposed by the introduction of the user diversity concept. Performance characterization is given in section 7.2.2.2.5. The described enhancement above is foreseen to be used together with the basic OSC candidate technique. Furthermore it is to be noted, that the concept is equally applicable to other candidates like co-TCH and alpha-QPSK.

7.1.3 Uplink concept

The uplink concept for OSC includes a subset of changes for the downlink. In particular two independent uplink transmissions are simultaneously received at the BTS. In the following the aspects of modulation and burst structure, usage of new training sequences and Tx pulse shapes, definition of associated control channel structure and application of the user diversity scheme are considered.

7.1.3.1 Modulation and burst structure

Modulation (i.e. GMSK) and burst structure (normal burst) are the same as for legacy traffic channels.

7.1.3.2 Usage of new training sequences

The mobiles use normal GMSK transmitter with OSC sub channel specific training sequence. Hence both sub channels can be distinguished by their training sequence, similarily as for downlink. A pair of legacy TSCs is used for legacy mobiles, whilst new OSC aware mobiles use new training sequences as depicted in section 7.1.2.1.2 . Training sequence on uplink is always identical to that employed for downlink.

7.1.3.3 Tx pulse shape

Different Tx pulse shapes may be used in uplink as proposed for downlink. Whilst the reuse of the GMSK pulse shape is proposed for the initial OSC concept, investigations on an optimized Tx pulse in uplink are FFS.

7.1.3.4 Associated control channels

FACCH transmission for full rate and halfrate OSC channel is identical to the legacy channel case.

SACCH transmission for full rate OSC channel may use option 1, 2 or 3 as depicted in section 7.1.2.1.7 for downlink.

SACCH transmission for half rate OSC channel may use option 1 or 2 as depicted in section 7.1.2.1.7 for downlink. In addition a third option is to use time shift of the SACCH channel as proposed for user diversity (see section 7.1.2.2.5.3, optimized user diversity half rate pattern 3).

7.1.3.5 User diversity

The user diversity scheme applied for downlink should also be used in uplink, i.e. the optimized user diversity pattern should be identical. Hence a signalling command refering to the user diversity pattern to be used on DL is also related to UL.

7.1.3.6 BTS receiver

BTS receiver may use e.g. Successive Interference Cancellation (SIC) or Joint Detection (JD) to receive signals from two mobiles on simultaneous sub channels with individual propagation paths. Thus, the uplink scheme can be seen as a 2x2 Multi User MIMO, where different propagation paths from two users provide the basis to fully utilize the degree of freedom of two receive antennas in typical BTS.

7.1.4 RR signalling

The following changes to RR signalling are needed:

- MS should provide OSC radio access capability indication.
- Channel assignment should include OSC sub channel information, e.g. in form of the new or the existing training sequence code number (4 bits).
- Channel assignment should include the specified user diversity pattern (2 bits for OSC FR channel and 2 bits for OSC HR channel) and the index for the mobile (2 bits) in case of user diversity support.

7.2 Performance Characterization

7.2.1 Link Level Performance

Link performance is characterized for sensitivity and for interference limited scenarios [7-2],[7-6],[7-7]. Simulations are performed for full rate and half rate AMR channels using some selected codec rates. Following fading radio channel profiles at GSM900 band are used:

• Typical urban, terminal speed 3 km/h, ideal frequency hopping (TU3iFH),

• Hilly terrain, terminal speed 100 km/h, ideal frequency hopping (HT100iFH).

Sensitivity and DARP test scenario-2 (DTS-2) are considered as noise and interference distortions, respectively. The baseline downlink receiver model is according to a generic DARP Phase 1 mobile station. OSC service is simulated with the same unmodified receiver. OSC signals are generated by mapping the users on QPSK constellation with equal transmission power between the sub channels. Signal rotation of $\pi/2$ is used. Tx pulse shaping is done according to Linearized GMSK pulse shaping filter, also the performance of alternative pulse shapes is evaluated.

7.2.1.1 Sensitivity Performance

For performance measurement the frame erasure rate (FER) is displayed over the signal to noise ratio (SNR).

7.2.1.1.1 Sensitivity in downlink

Results are presented for the case of equal power on the subchannels (SCPIR = 0 dB) in subsection 7.2.1.1.1.1 and for the case of unequal power on the subchannels in subsection 7.2.1.1.1.2 .

7.2.1.1.1.1 Sensitivity in downlink without sub channel specific power control

Different receiver types have been assumed such as DARP phase 1 with usage of legacy TSC"s on both subchannels, with usage of new TSC on paired subchannel and OSC aware receiver benefitting from the knowledge of the training sequences employed on both subchannels.

Performance for DARP Phase 1 receiver and legacy training sequences

Legacy training sequence codes are applied to the sub channels, in that legacy training sequence pair TSC0 and TSC2 has been used. In Figure 7-6 and Figure 7-7 the downlink sensitivity performance of OSC is evaluated for some codecs of AMR Full Rate (AFS) and AMR Half Rate (AHS) without and with ideal frequency hopping respectively.

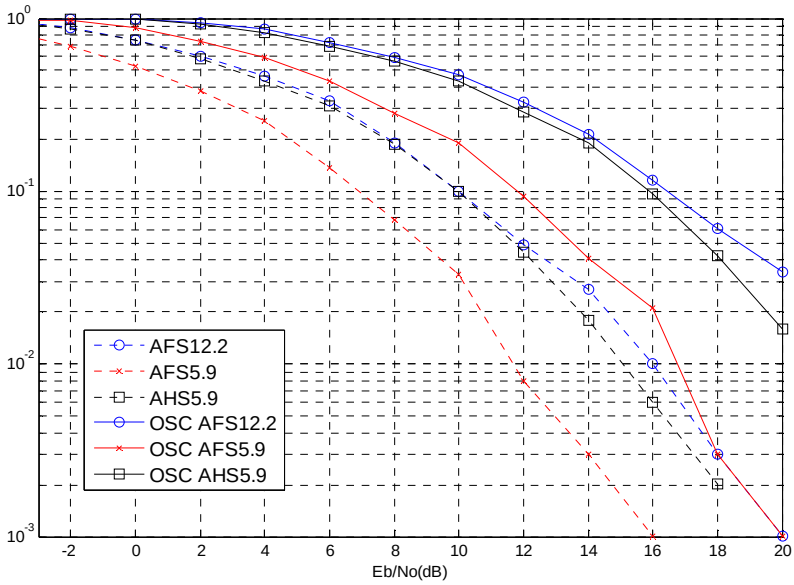

Figure 7-6: DL sensitivity FER performance in TU3nFH of generic DARP phase 1 MS receiving an OSC sub channel with AMR FR 5.9, 12.2 and AMR HR 5.9

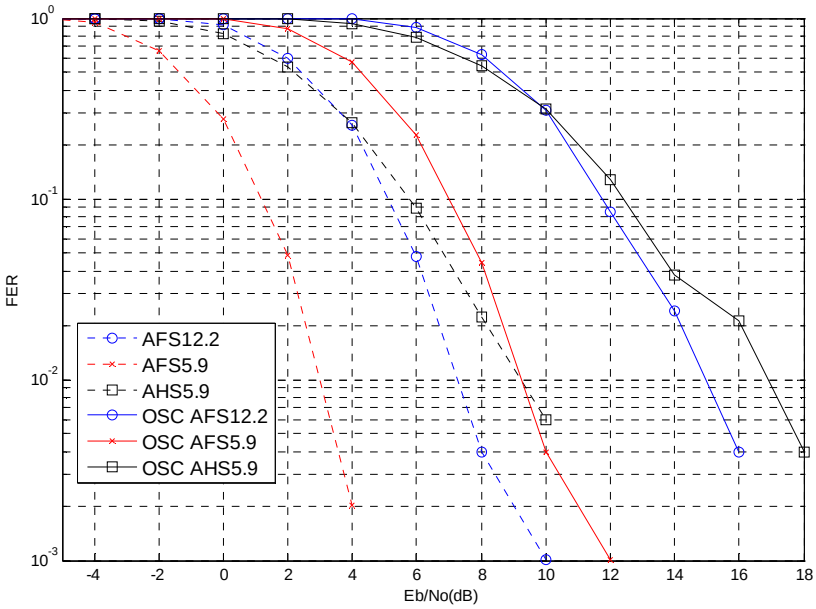

Figure 7-7: DL sensitivity FER performance in TU3iFH of generic DARP phase 1 MS receiving an OSC sub channel with AMR FR 5.9, 12.2 and AMR HR 5.9

In Figure 7-8 the downlink sensitivity performance of OSC is evaluated for different transmit pulse shaping filters. Simulated pulse shaping filters are Linearized GMSK filter and Root Raised Cosine filters with normalized bandwidths of 180, 240 and 270 kHz. Sensitivity performance is clearly improved with RRC filters.

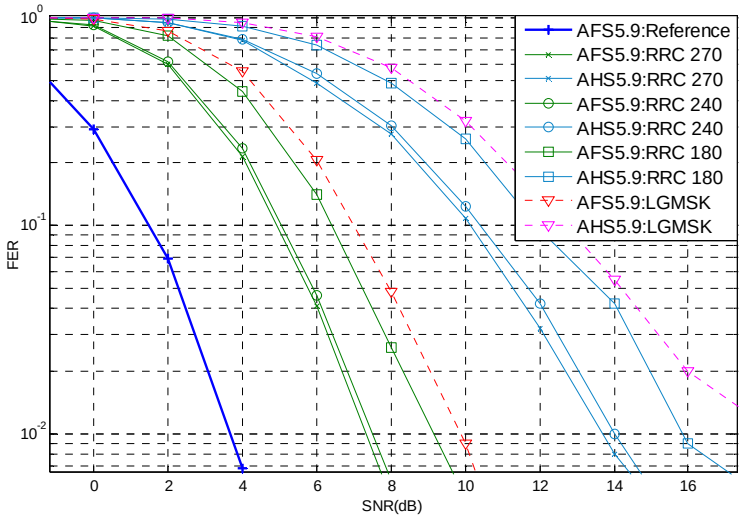

Figure 7-8: DL sensitivity FER performance in TU3iFH of generic DARP phase 1 MS receiving an OSC sub channel with AMR FR 5.9 and HR 5.9 with different transmit pulse shaping filters

In Figure 7-9 the downlink sensitivity performance of OSC in Hilly Terrain 100 km/h radio propagation channel is evaluated against reference.

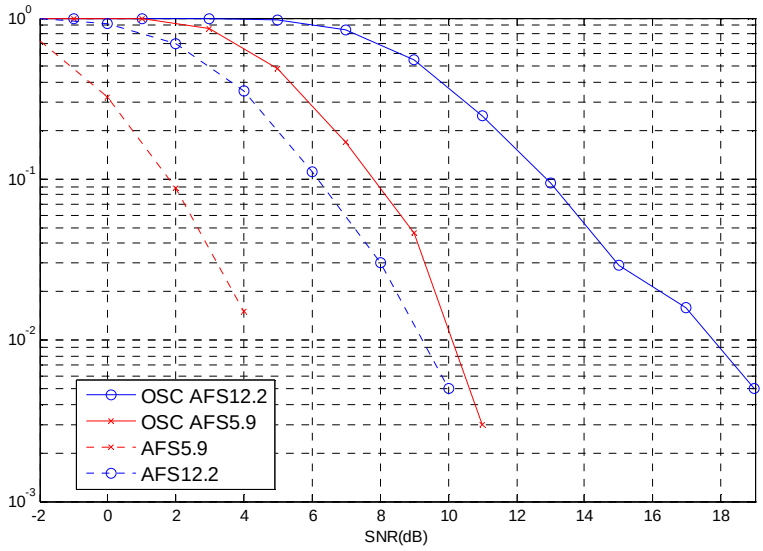

Figure 7-9: DL sensitivity FER performance in HT100iFH of generic DARP phase 1 MS receiving an OSC sub channel with AMR FR 5.9 and 12.2

It is shown that the performance of a legacy DARP 1 MS receiving an OSC sub channel is adequate in average network conditions, and more robust AMR channels can also provide sufficient coverage. Sensitivity would be significantly improved by more optimum transmit filter than Linearized GMSK filter. MUROS downlink concept also works in difficult radio propagation conditions, but the usage of high rate AMR codecs is limited to good SNR region.

Performance for a DARP phase 1 receiver in case of a new training sequence on paired sub channel

Furthermore investigations with a non-OSC aware type of receiver, such as a DARP phase 1 receiver have been carried out using different Tx pulse shapes (linearized GMSK, RRC 270 kHz) for the case of reusing the existing TSCs and the case using a new set of TSCs as proposed in section 7.1.2.1.2 for the paired sub channel. Results are reported in Figure 7-10.

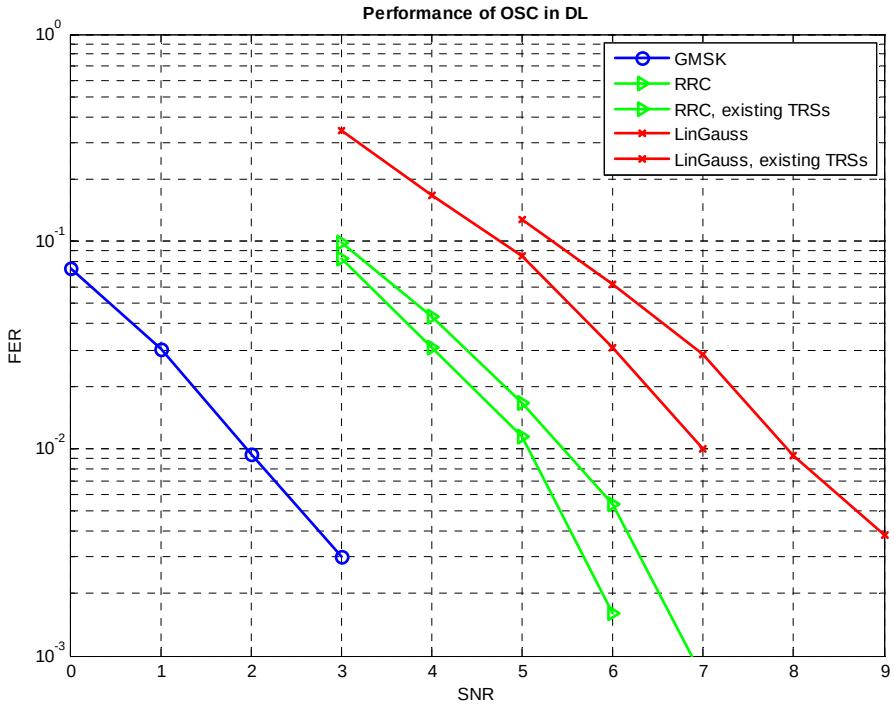

Figure 7-10: FER versus SNR for AMR FR 5.9 at TU3 iFH for DARP phase 1 receiver and usage of legacy TSCs only or mix of legacy and new TSC"s

It can be seen that the performance loss related to legacy full rate both depends on the Tx pulse shape and the used set of TSCs for the paired sub channel. The performance loss is depicted in Table 7-12.

Table 7-12 Link Performace and Loss to Reference for AMR FR 5.9 @ FER=1%

Configuration	SNR for FER=1%	Loss to Reference
GMSK (Reference)	1.9 dB	-
RRC 270kHz, new TSC pair	5.1 dB	3.2 dB
RRC 270 kHz, existing TSC pair with lowest x-correlation	5.4 dB	3.5 dB
Linearised Gaussian, new TSC pair	7.0 dB	5.1 dB
Linearised Gaussian, existing TSC pair with highest cross-correlation	7.9 dB	6.0 dB

Performance for OSC aware receiver and usage of new training sequences

The FER versus SNR is shown in Figure 7-11. It can be seen that OSC would need about 2.6 - 3.2 dB higher Es/No for doubled capacity in sensitivity limited scenarios, i.e. Eb/No is about the same as for related GMSK service, depending on the receiver type (2.6 dB for OSC aware receiver and 3.2 dB for DARP phase 1 receiver).

Since QPSK in downlink may need to reduce transmitter power compared to GMSK due to higher PAR by 2.2 dB in case of RRC pulse shape, further due to the OSC aware receiver, i.e. the receiver which has knowledge about the training sequences of both sub channels using this information for channel estimation of the paired interfering sub channel and which needs 2.6 dB higher Es/No, this yields a 4.8 dB lower link budget for doubled capacity in case of sensitivity limited scenarios. For comparison AMR HR 5.9 needs about 7dB higher Es/No than AMR FR 5.9, thus fullrate orthogonal sub channel could improve HR coverage by about 2 dB in TU3 iFH. Whilst for GMSK legacy AMR, TX pulse shape was assumed to be linearised GMSK, RRC filter with 3 dB double sided bandwidth of 270 kHz was assumed in use for OSC FR, if not otherwise stated. Both receivers, named "GMSK" and "GMSK RX for OSC" in the figures below, are SAIC type receivers. Performance of non-DARP phase 1 legacy MSes is FFS.

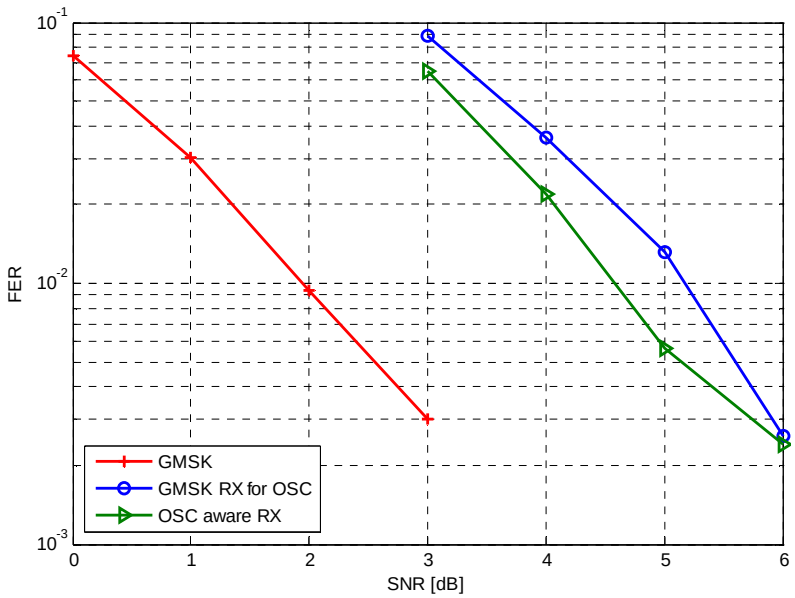

Figure 7-11: FER versus SNR for AMR FR 5.9 at TU3 iFH for DARP Phase 1 and OSC aware receivers with RRC270 TX pulse shape in case of OSC

7.2.1.1.1.2 Sensitivity in downlink with subchannel specific power control

In this section, simulation results are shown to verify how the SAIC (i.e. DARP phase 1) and non-SAIC mobiles behave in the sensitivity limited cases when receiving signals on downlink with sub-channel power control. TU 3 ideal frequency hopping channel is simulated under sensitivity limited conditions with AWGN noise interferer. It can be seen from Figure 7-12 that the performance of SAIC mobile both on strong and weak channels using the rectangular constellation points possible with 8-PSK modulator is acceptable. Also from Figure 7-13, it can be seen that legacy non-

SAIC mobiles can also decode the OSC signal in downlink if they are multiplexed on the stronger channel. It should be noted that all the bursts used a rectangular constellation here (i.e the case of maximum power imbalance between the subchannels). Further granularity in power control steps could be obtained by varying the constellation diagram as depicted in section 7.1.2.2.2 but this exercise is not repeated here. Further, it can also be noted that as long as the mobiles are multiplexed on the strong channel, the performance of the legacy mobiles with and without SAIC in sensitivity limited scenarios is quite close as seen from the performance of user 2 – who is the stronger user in Figure 7-12 and Figure 7-13.

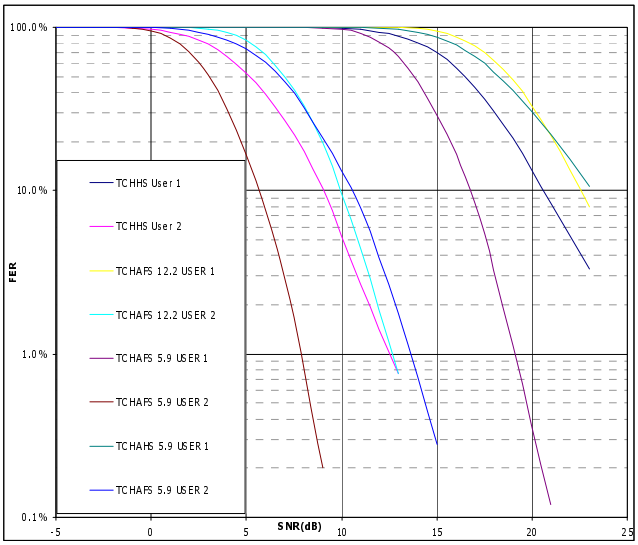

Figure 7-12: Sensitivity performance – SAIC ON

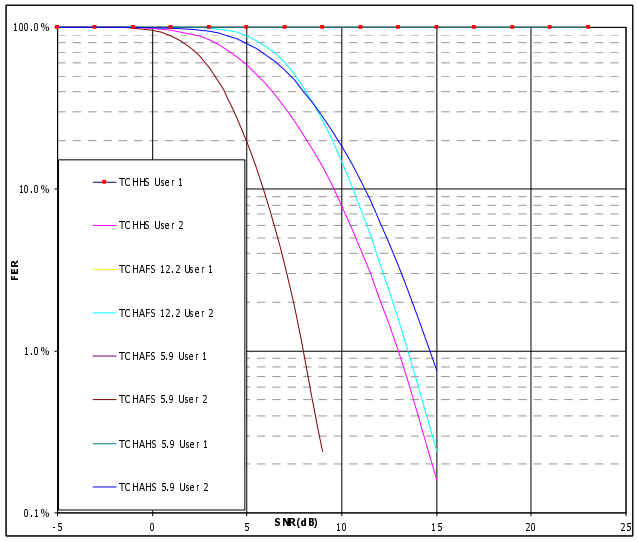

Figure 7-13: Sensitivity performance – SAIC OFF

7.2.1.1.2 Sensitivity in uplink

For uplink sensitivity simulations a SIC receiver has been used (Successive Interference Cancellation). Performance for IRC receiver type (reference) and SIC receiver is shown in Figure 7-14 for different level offsets between coincident users, i.e. SCPIR = -20dB ... +10dB (related to wanted subchannel). FER values are normalized values so that reference AMR HR 7.4 exhibits 1% FER at SNR = 0 dB. It seems that about 2.6 dB loss in coverage is experienced when other orthogonal signal is 10dB higher than wanted signal when SIC receiver is used. At higher SNR levels higher offsets are tolerated. For SCPIR = - 20 dB, a performance loss of almost 6 dB is observed compared to the reference.

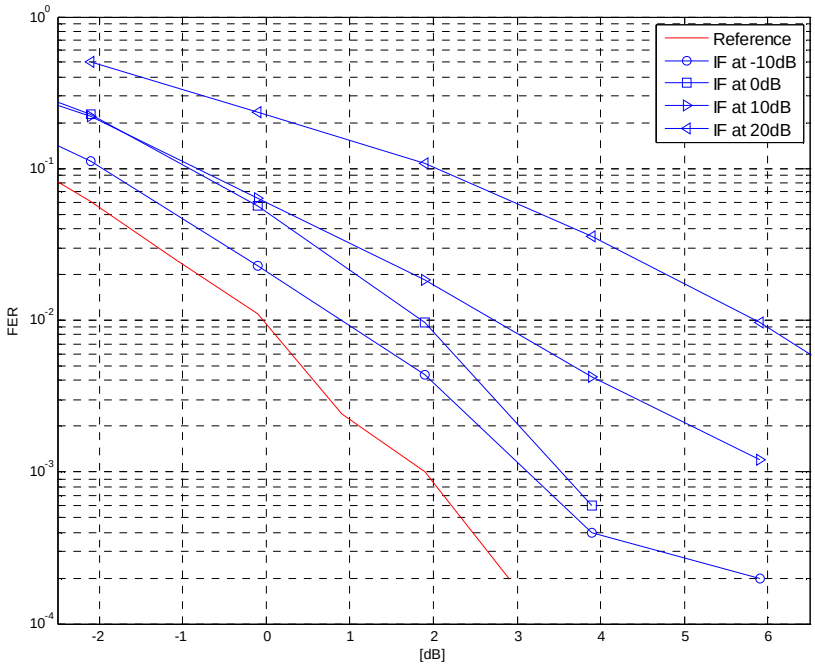

Figure 7-14: UL sensitivity FER performance of a SIC receiver receiving an OSC sub channel with AMR HR 7.4 in dependence of SNR

OSC concept evaluation in uplink shows that low complexity SIC equalizer can support two subchannels with 2-3 dB difference to the single user uplink channel for SCPIR between -10 dB...10 dB, and even somewhat higher ratios can be tolerated with moderate SNR performance loss.

7.2.1.2 Interference Performance

7.2.1.2.1 Interference limited performance in downlink

7.2.1.2.1.1 Interference performance in downlink without subchannel specific power control

Performance for MUROS Test Scenario 1

See performance evaluation in section 7.2.1.2.1.2 .

Performance for MUROS Test Scenario 2

Different receiver types have been assumed such as DARP phase 1 with usage of legacy TSC"s on both subchannels, with usage of new TSC on paired subchannel and OSC aware receiver benefitting from the knowledge of the training sequences employed on both subchannels.

Performance for DARP Phase 1 receiver with legacy training sequences

For performance measurement the frame erasure rate (FER) is displayed over the the carrier to interferer ratio (CIR). The CIR for MTS-2 scenario is related to the dominant interferer designated as C/I_0. In case of OSC the power of the wanted sub channel is considered. The other orthogonal sub channel is not taken into account in C/I calculation. Performance was compared applying linearized GMSK pulse shape filter.

In Figure 7-15 the downlink performance of MTS-2 is evaluated against reference for some codecs of AMR Full Rate (AFS) and AMR Half Rate (AHS) with ideal frequency hopping.

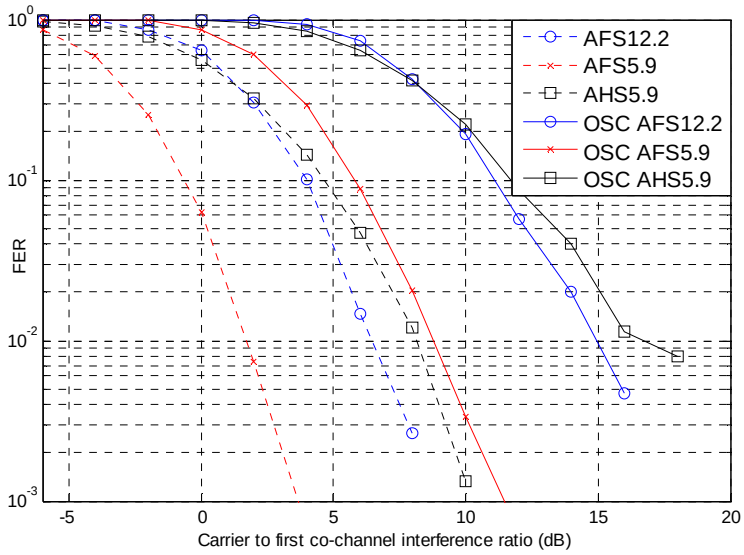

Figure 7-15: DL MTS-2 FER performance in TU3iFH of generic DARP phase 1 MS receiving an OSC sub channel with AMR FR 5.9, AMR FR 12.2 and AMR HR 5.9

Performance comparison at FER=1% is captured in Table 7-13 for the three invstigated AMR codec types.

Table 7-13: Link Performace and Loss to Reference for AMR FR 5.9 @ FER=1%

Configuration	C/I_0 for FER=1%	Loss to Reference
OSC AMR FR 12.2	15.0 dB	8.6 dB
OSC AMR FR 5.9	8.9 dB	7.3 dB
OSC AMR HR 5.9	17.0 dB	8.7 dB

Performance for OSC aware receiver and usage of new training sequences

Interference performance shown in Figure 7-16 seems to have about similar 2.6-3.4dB difference as in sensitivity limited case. Again RRC 270 Tx pulse shape was used in this evaluation as well as new TSC for the paired subchannel. Performance is depicted for both a DARP phase 1 (GMSK RX for OSC) and an OSC aware MS. For comparison AMR HR 5.9 needs about 7dB higher C/I than AMR FR 5.9, thus orthogonal sub channel can improve HR performance by about 4 dB in TU3 iFH.

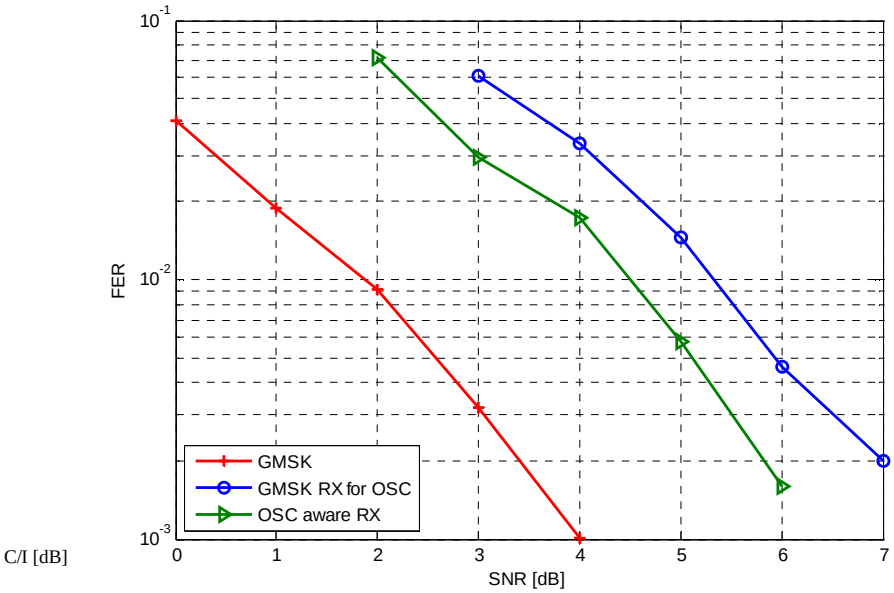

Figure 7-16: FER for AMR FR 5.9 in TU3 iFH at MTS-2 for DARP phase 1 receiver (GMSK RX for OSC) and OSC aware receiver.

7.2.1.2.1.2 Interference performance in downlink with subchannel specific power control

Simulation parameters are depicted in Table 7-14.

Table 7-14: Simulation settings for downlink interference performance with subchannel specific power control

Parameter	Value
Channel	TU 3
Frequency hopping	Ideal
AMR modes	TCHHS, TCHAFS 12.2, TCHAFS 5.9, TCHAHS 5.9
Antenna diversity (TX and RX)	Off
SAIC	On / Off
External Interference	Single Co-channel (MTS-1)
External Interferer Modulation	GMSK
C/I	Carrier Power (includes both users) / Power of External Interferer
TSCs	TSC-0 legacy and TSC-0 from new set shown in section 1.2.1.2
Number of frames	10000 frames per each C/I point

Multiplexing a SAIC mobile with a legacy non-SAIC mobile

In this section the case of multiplexing a SAIC mobile with a non-SAIC mobile is studied. It should be noted that one of the two mobiles use the newer TSC hence they are not entirely legacy in that sense. However, apart from the knowledge of the new TSC, nothing else is modified for the SAIC algorithm. Hence, the SAIC mobile with the knowledge of new TSC here might as well represent a OSC aware mobile.

The multiplexing case studied here is the case when the SAIC mobile is on the weaker sub-channel and the legacy non-SAIC mobile is on the stronger sub-channel. This is the typical multiplexing use case to support legacy non-SAIC mobiles in the field using OSC. The results are shown in Figures 7-17, 7-18, 7-19 and 7-20. It can be observed that to multiplex 4 users (2 of which are legacy non-SAIC mobiles) using half rate codecs – TCHHS or TCHAHS 5.9, C/Is around 10 to 20 dB are sufficient in the cell. To multiplex full rate users using TCHAFS 5.9 for instance C/I ratios from 3 to 15 dB are sufficient. Thus it can be seen that multiplexing a legacy non-SAIC mobile with a SAIC mobile using OSC is feasible using both full rate and half rate codec modes. Hence, up to four users including legacy non-SAIC mobiles could be multiplexed using OSC in downlink using the proposed power control strategy.

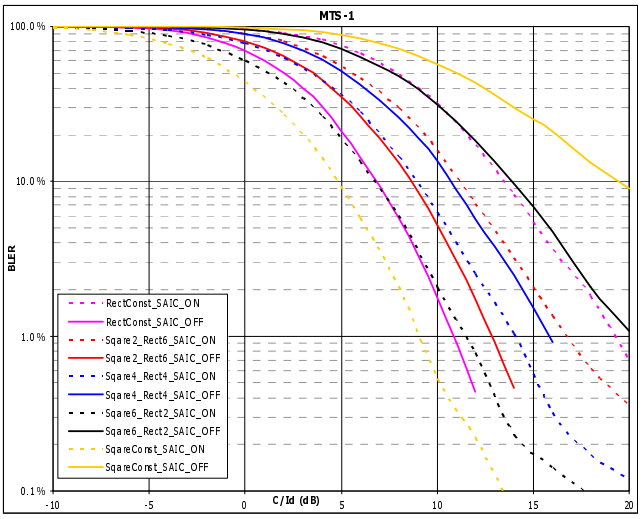

Figure 7-17 TCH:HS

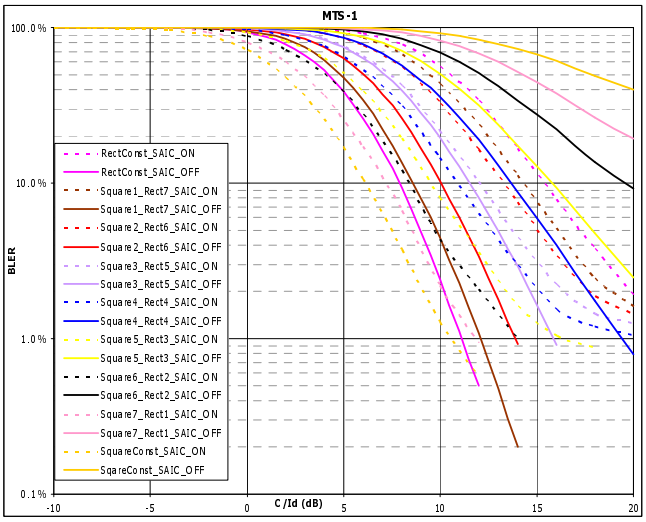

Figure 7-18 TCHAFS 12.2

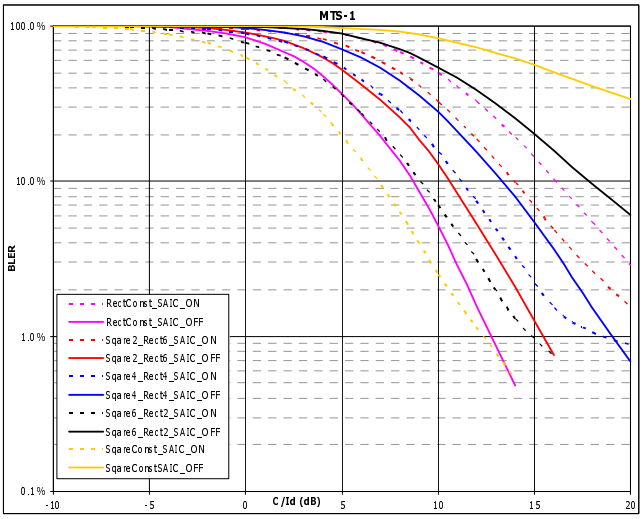

Figure 7-19 TCHAHS 5.9

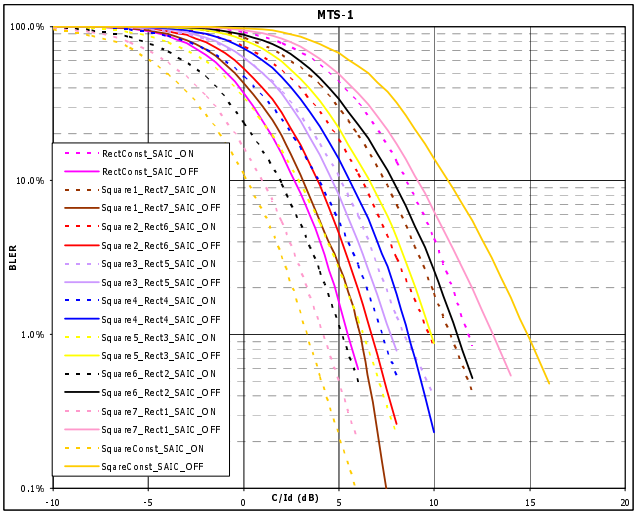

Figure 7-20 TCHAFS 5.9

Legend: In the figures above, the usage of rectangular and square constellations is switched using a predetermined pattern of length 8. For instance, Square1_Rect7_SAIC_ON depicts the performance of a SAIC mobile when the constellation diagram is switched between 1 square (QPSK burst) and 7 rectangular bursts alternatively. It should be noted that when the rectangular burst is used, the signal corresponding to the SAIC mobile is attenuated (by approximately 7.6592 dB). RectConst_SAIC_ON refers to the case when all the bursts use the depicted rectangular constellation (performance of SAIC mobile which in this case is always on the weaker channel is depicted) and SquareConst_SAIC_OFF referes to the case when all the bursts use QPSK (performance of non SAIC mobile is depicted).

Multiplexing two SAIC mobiles

Multiplexing two SAIC mobiles is the easier case compared to the case studied in section above. The advantage of having 2 SAIC mobiles is that multiplexing could be achieved with much lower C/Is in the cell as seen from Figures 7-21, 7-22, 7-23 and 7-24. Here user 2 is always put on the strong channel and user 1 is put on the weaker channel. It can be seen that with 2 SAIC mobiles, C/I ratios in the range of -3 to 12 dB are sufficient to support simultaneous voice call between two mobiles on the downlink using TCHAFS 5.9 codec for instance. It should again be noted that one of the two SAIC mobiles used the orthogonal TSC from the new TSC set and hence can be considered as a OSC aware mobile. Alternatively two TSCs from the legacy set which have good orthogonality could also be chosen thereby multiplexing 2 legacy SAIC mobiles simultaneously. This case however has not been investigated here.

7.2.1.3 Results from: MUROS – Performance of Legacy MS

Text in this section originates by Nokia Corporation in [7-10].

In this section, the sensitivity and interference performance of both legacy non-DARP MS and legacy DARP MS receiving a MUROS sub channel is presented. For interference performance verification the four MUROS Test Scenarios (MTS1-4) described in chapter 5 are used.

7.2.1.3.1 Simulation Assumptions

7.2.1.3.1.1 Legacy Terminals

The legacy DARP receiver applied in this section is a DARP phase I capable terminal. Such DARP terminals are widely present in the market. The legacy non-DARP receiver applied in this section is also present in the market.

7.2.1.3.1.2 Transmitted MUROS Signal

In this section, the DL MUROS signal is generated by QPSK symbol mapping with $\pi/2$ rotation and linearized GMSK TX pulse shape as illustrated in Figure 7-25. This corresponds to the OSC technique presented by NSN in [7-2].

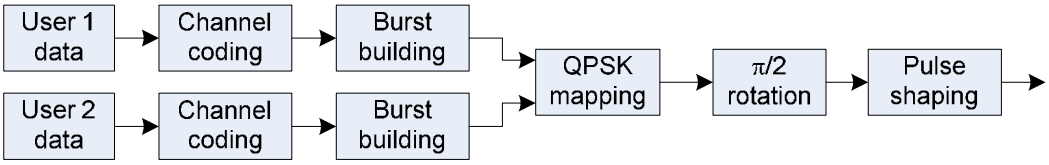

Figure 7-25: Block diagram of MUROS TX by mapping two users on BB and transmitted as a QPSK modulated signal

As described above legacy training sequence codes (TSC) are applied to the first MUROS sub channel to make it fully compatible with legacy MS. For the MUROS second sub channel, the orthogonal TSCs proposed in [7-2] are assumed. The pair TSC 0 is chosen from the combined TSC set for the simulations. DTX is not applied.

7.2.1.3.1.3 MUROS Interference Models

The four MUROS Test Scenarios (MTS1-4) specified in this TR and Adjacent Channel Interference (ACI) have been used for verifying the interference performance of a legacy non-DARP and legacy DARP MS receiving a MUROS sub channel.

For MTS modulation the GMSK and MUROS modulated interference agreed for MTS1-4 in this TR are included. For ACI both the GMSK and MUROS modulation have been used as well. Only lower band ACI (-200 kHz) is included since the effect of upper band ACI (+200 kHz) is similar.

In [7-11] it was shown that the performance of a legacy DARP MS receiving a MUROS sub channel is more or less independent of the interference modulation type as long as GMSK is not applied for the interferer modulation.

7.2.1.3.1.4 Other Simulation Parameter

The performance is presented for TCH/AFS 12.2, TCH/AFS 5.9 and AHS 5.9. A typical urban channel profile, terminal speed 3 km/h (TU3) and frequency hopping (FH) in the 900 MHz band have been used for the DL MUROS simulations. Typical MS impairments are included in the simulations.

7.2.1.3.2 Downlink Performance Results

The results in this section cover frame erasure rate (FER) as a function of C/I1 where C denotes the total power of the received MUROS signal (i.e. carrying 2 sub channels) and I1 denotes the power of the strongest co-channel interferer.

The presented performance is for the first MUROS sub channel containing the legacy TSC0. The performance of the second MUROS sub channel is not considered in this section, since changes are required to the MS receiver in order to cope with the orthogonal TSCs presented in [7-2]. However, when the two MUROS sub channels have equal power the performance of the second channel can be assumed to be on par with the first sub channel as noted in [7-12].

First the sensitivity performance is presented in subsection 7.2.1.3.2.1, and then the interference performance for the two synchronous scenarios MTS1+2 are presented in subsection 7.2.1.3.2.2 and 7.2.1.3.2.3 respectively. The performance for the two asynchronous scenarios MTS3+4 are presented in subsection 7.2.1.3.2.4 and 7.2.1.3.2.5 respectively. Finally the ACI performance is presented in subsection 7.2.1.3.2.6.

7.2.1.3.2.1 Sensitivity Performance

The sensitivity performance of a legacy DARP MS receiving a MUROS sub channel is presented in Figure 7-26.

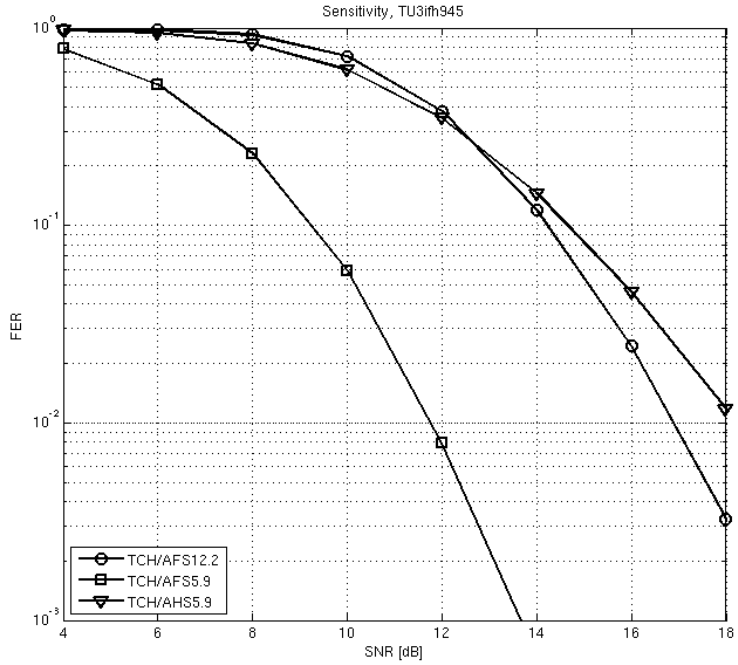

Figure 7-26: DL sensitivity performance of a legacy DARP MS receiving a MUROS sub channel

7.2.1.3.2.2 MTS-1 Performance

The performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel when a single synchronous co-channel interferer is present are shown in Figure 7-27 and Figure 7-28 respectively for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9.

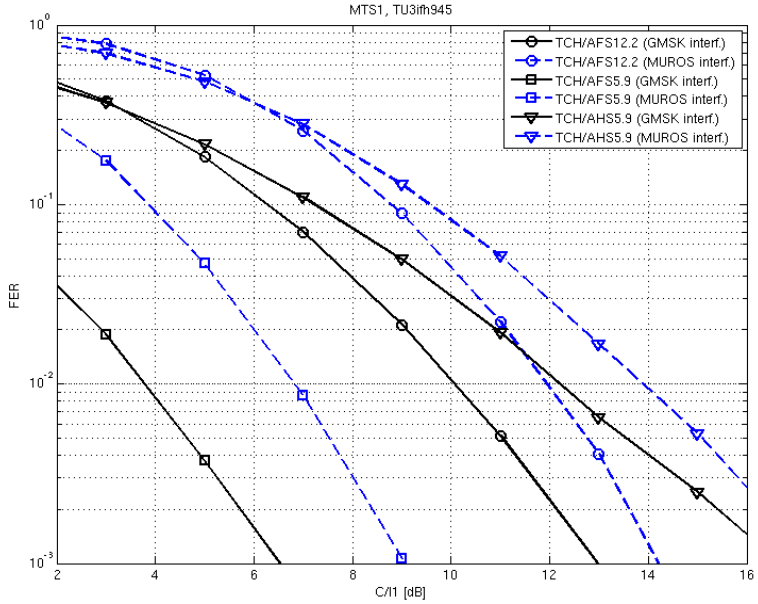

Figure 7-27:DL Co-channel interference performance (MTS1) of a legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

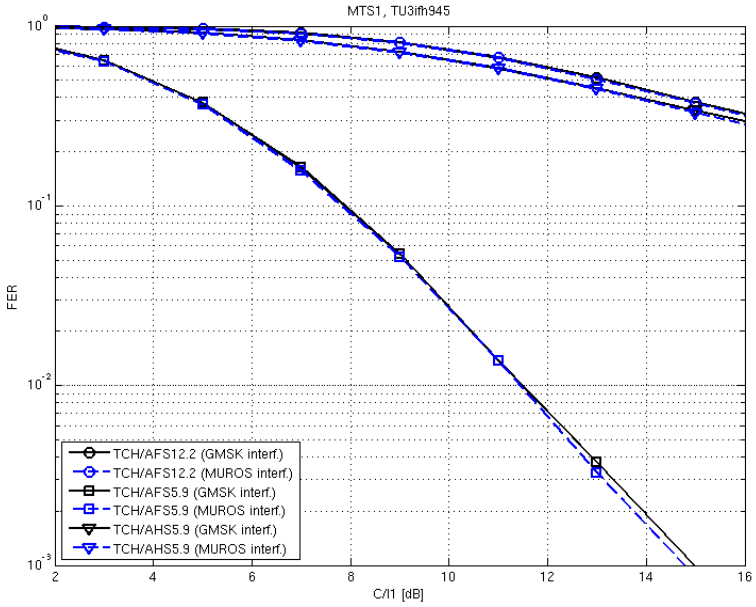

Figure 7-28: DL Co-channel interference performance (MTS1) of a legacy non-DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

7.2.1.3.2.3 MTS-2 Performance

The performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel when mixed synchronous interference is present are shown in Figure 7-29 and Figure 7-30 respectively for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9.

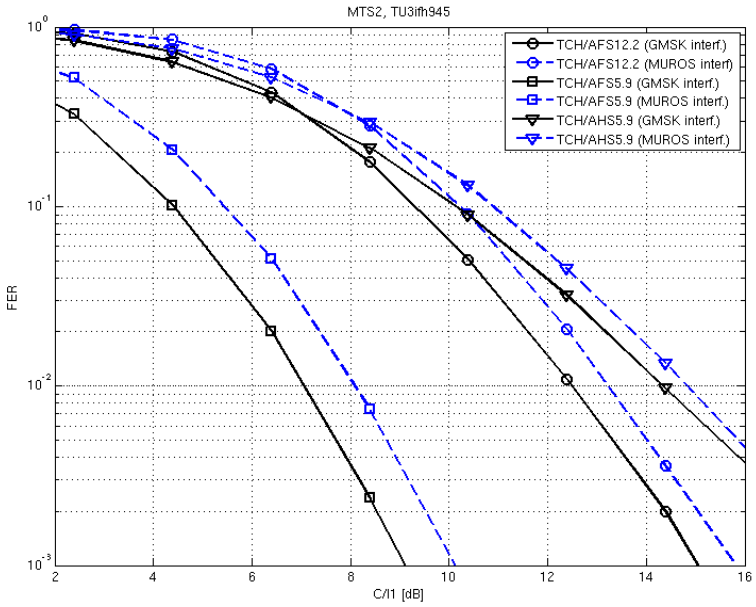

Figure 7-29: DL Mixed interference performance (MTS2) of a legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

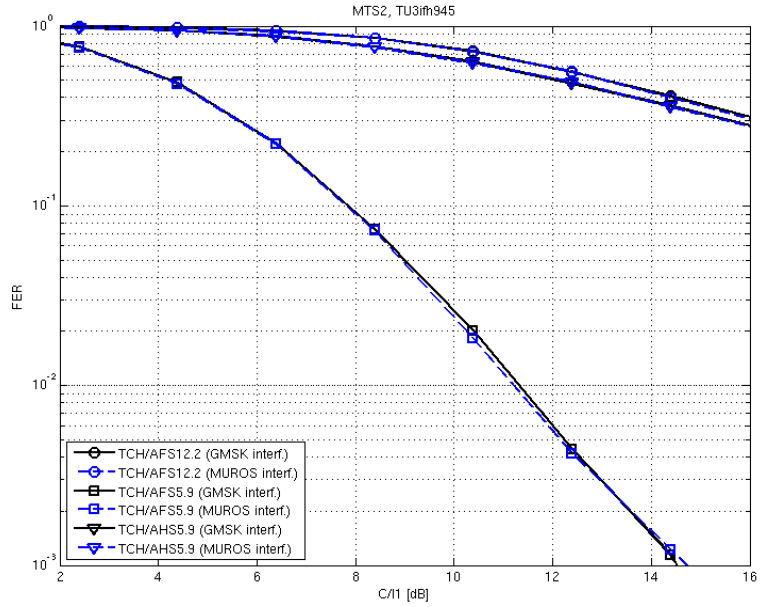

Figure 7-30: DL Mixed interference performance (MTS2) of a legacy non-DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

7.2.1.3.2.4 MTS-3 Performance

The performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel when a single asynchronous co-channel interference is present are shown in Figure 7-31 and Figure 7-32 respectively for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9.

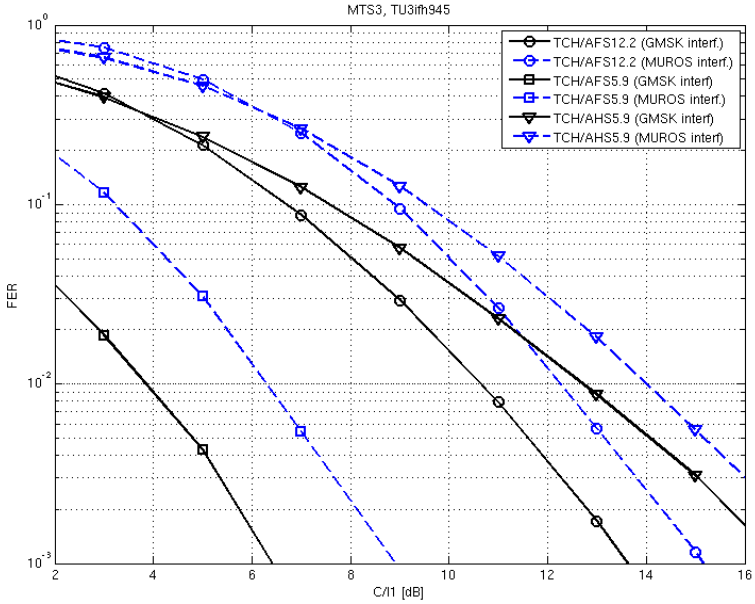

Figure 7-31: DL Asynchronous Co-channel interference performance (MTS3) of a legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

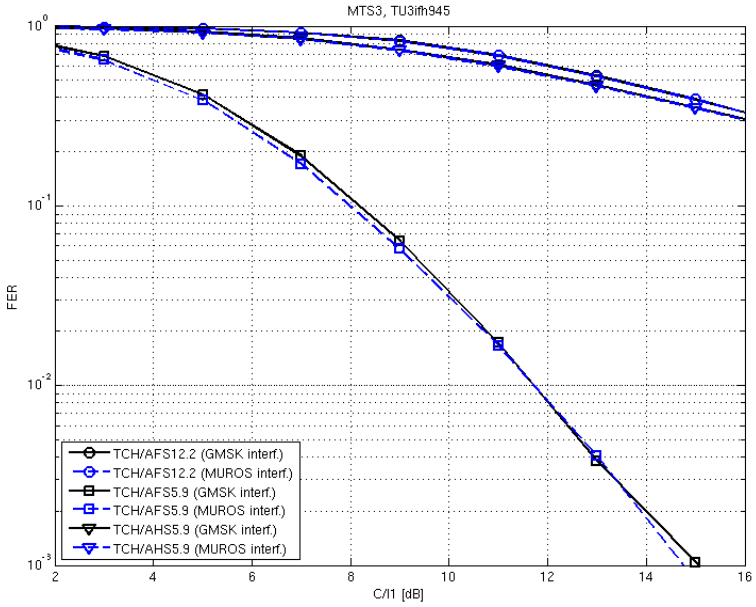

Figure 7-32: DL Asynchronous Co-channel interference performance (MTS3) of a non-legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

7.2.1.3.2.5 MTS-4 Performance

The performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel when mixed synchronous and asynchronous interference are present are shown in Figure 7-33 and Figure 7-34 respectively for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9.

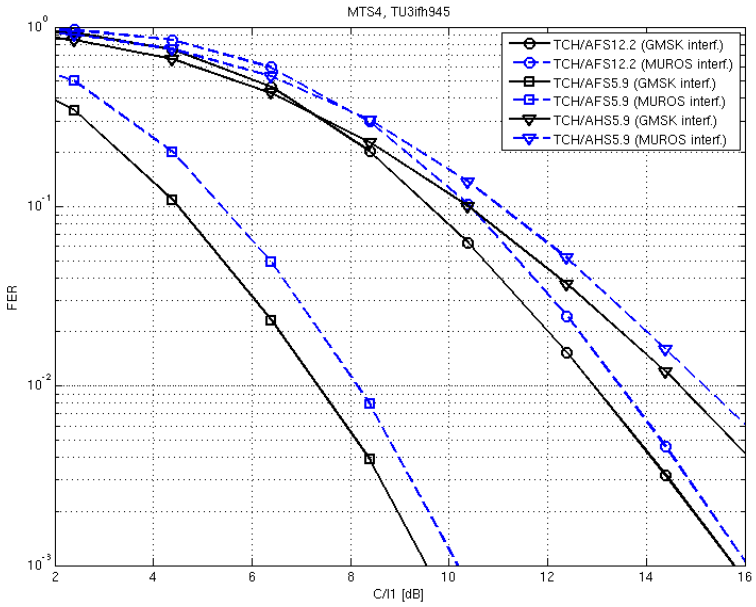

Figure 7-33: DL synchronous and asynchronous mixed interference performance (MTS4) of a legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

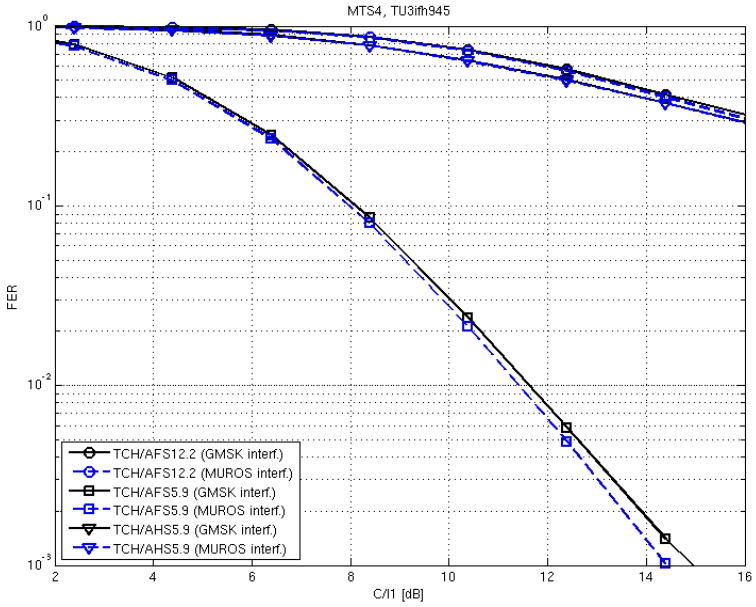

Figure 7-34: DL synchronous and asynchronous mixed interference performance (MTS4) of a legacy non-DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

7.2.1.3.2.6 ACI Performance

The performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel when lower band adjacent channel interference (-200 kHz) is present are shown in Figure 7-35 and in Figure 7-36 respectively for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The 3GPP ACI performance requirements for the three AMR codecs are indicated in the figures as well by red marks for information.

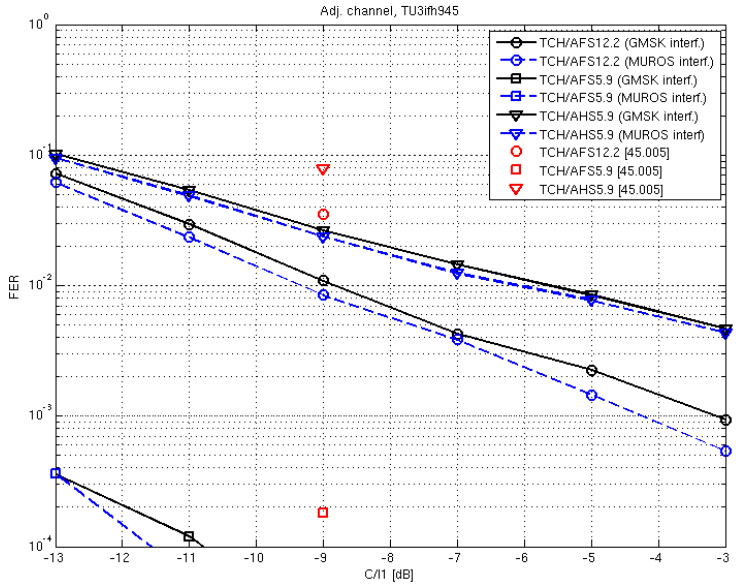

Figure 7-35: Adjacent channel interference performance (lower band) of a legacy DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

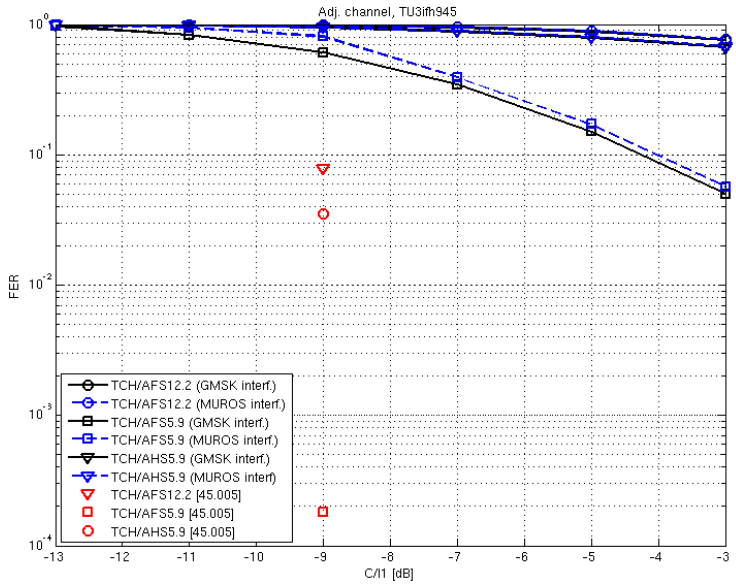

Figure 7-36: Adjacent channel interference performance (lower band) of a legacy non-DARP MS receiving a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

7.2.1.3.3 Summary of results

This section presented the sensitivity and interference performance of a legacy DARP MS and a legacy non-DARP MS receiving a MUROS sub channel. For the interference performances both the MTS1-4 interference scenarios and ACI scenario were used with the interferer modulation type being either: GMSK or MUROS.

As expected it was shown that legacy DARP MS are better to cope with a MUROS sub-channel than legacy non-DARP MS. Furthermore it can be observed that a power balancing between the two MUROS sub-channels are desirable in order to achieve the full benefit of MUROS.

7.2.2 Network Level Performance

7.2.2.1 Network Configurations

In order to evaluate the system impact of OSC, network simulations for the agreed MUROS network configurations were carried out. Studied network configurations are shown in Table 7-15 and the used channel modes and channel adaptation types in Table 7-16. Adaptation between OSC and non-OSC channel was based both on load and quality measurements. DL receiver type was DARP Phase 1. The employed BTS antenna type had a 65° horizontal half power beamwidth [7-8].

Table 7-15: Studied network configurations

Parameter	MUROS-1	MUROS-2	MUROS-3 a)	MUROS-3 b)
Frequency band (MHz)	900	900	1800	1800
Cell radius	500 m	500 m	500 m	500 m
Bandwidth	4.4 MHz	11.6 MHz	2.6 MHz	2.6 MHz
Guard band	0.2 MHz	0.2 MHz	0.2 MHz	0.2 MHz
# channels excluding guard band	21	57	12	12
# TRX	4	6	4	4
BCCH frequency reuse	4/12	4/12	N.A.	N.A.
TCH frequency reuse	1/1	3/9	1/3	1/1
Frequency Hopping	Synthesized	Baseband	Synthesized	Synthesized
Length of MA (# FH frequencies)	9	5	4	4
Fast fading type	TU	TU	TU	TU
BCCH or TCH under interest	Both	Both	TCH	TCH
Network sync mode	sync	sync	sync	sync

Table 7-16: Studied channel modes and channel adaptation types

Channel Mode Adaptation	Channel modes
Type A0	GSM HR
Type A1	GSM HR <-> OSC HR
Type B0	AFS 12.2
Type B1	AFS 12.2 <-> OSC AFS 12.2
Type C0	AFS 5.9
Type C1	AFS 5.9 <-> OSC AFS 5.9
Type D0	AHS 5.9
Type D1	AHS 5.9 <-> OSC AHS 5.9

7.2.2.2 Performance results

System performance results in terms of blocking and DL TCH FER are presented in this section. The following criteria for definition of minimum call quality performance were used:

- blocked calls < 2 %

- call average TCH FER:

  - channels using full rate coding < 2% for at least 95% of the users
  - channels using half rate coding < 3% for at least 95% of the users

7.2.2.2.1 MUROS-1

MUROS-1 capacity numbers are presented in Table 7-17. A0 (=GSM HR) and C0 (= AFS 5.9) were blocking limited, whereas all the other cases were quality limited.

Table 7-17: MUROS-1 performance results

Type	Description	Spectral Efficiency [Users/MHz/site]	Hardware Efficiency [Users/TRX]	Limiting factor
A0	HR	36.21	14.48	Blocked calls
A1	MUROS HR	32.10	12.84	Bad quality calls (3%)
B0	AFS 12.2	14.23	5.69	Bad quality calls (2%)
B1	MUROS AFS 12.2	14.31	5.72	Bad quality calls (2%)
C0	AFS 5.9	14.90	5.96	Blocked calls
C1	MUROS AFS 5.9	28.09	11.24	Bad quality calls (2%)
D0	AHS 5.9	26.41	10.56	Bad quality calls (3%)
D1	MUROS AHS 5.9	23.04	9.22	Bad quality calls (3%)

7.2.2.2.2 MUROS-2

MUROS-2 capacity results are shown in Table 7-18. In this loose frequency reuse case (BCCH 4/12 and TCH 3/9) A1. B1 and D1 were quality limited and all the other cases were blocking limited.

Table 7-18: MUROS-2 performance results

Type	Description	Spectral Efficiency [Users/MHz/site]	Hardware Efficiency [Users/TRX]	Limiting factor
A0	HR	20.94	14.47	Blocked calls
A1	MUROS HR	42.62	29.44	Bad quality calls (3%)
B0	AFS 12.2	9.71	6.71	Blocked calls
B1	MUROS AFS 12.2	13.78	9.52	Bad quality calls (2%)
C0	AFS 5.9	9.66	6.68	Blocked calls
C1	MUROS AFS 5.9	20.93	14.46	Blocked calls
D0	AHS 5.9	20.91	14.45	Blocked calls
D1	MUROS AHS 5.9	28.59	19.75	Bad quality calls (3%)

7.2.2.2.3 MUROS-3

Capacity results for MUROS-3 are shown in Table 7-19 and Table 7-20. Most of the cases where quality limited in this tight frequency reuse network (TCH reuse 1/3 for MUROS-3 a) or 1/1 for MUROS-3 b), respectively).

Table 7-19: MUROS-3 a) performance results

Type	Description	Spectral Efficiency [Users/MHz/site]	Hardware Efficiency [Users/TRX]	Limiting factor
A0	HR	59.08	11.82	Bad quality calls (3%)
A1	MUROS HR	51.59	10.32	Bad quality calls (3%)
B0	AFS 12.2	21.85	4.37	Bad quality calls (2%)
B1	MUROS AFS 12.2	21.58	4.32	Bad quality calls (2%)
C0	AFS 5.9	32.80	6.56	Blocked
C1	MUROS AFS 5.9	40.44	8.09	Bad quality calls (2%)
D0	AHS 5.9	42.41	8.48	Bad quality calls (3%)
D1	MUROS AHS 5.9	37.99	7.60	Bad quality calls (3%)

Table 7-20: MUROS-3 b) performance results

Type	Description	Spectral Efficiency [Users/MHz/site]	Hardware Efficiency [Users/TRX]	Limiting factor
A0	HR	73.86	14.77	Blocked calls
A1	MUROS HR	66.44	13.29	Bad quality calls (3%)
B0	AFS 12.2	29.58	5.92	Bad quality calls (2%)
B1	MUROS AFS 12.2	29.76	5.95	Bad quality calls (2%)
C0	AFS 5.9	31.82	6.36	Blocked calls
C1	MUROS AFS 5.9	58.98	11.80	Bad quality calls (2%)
D0	AHS 5.9	56.97	11.39	Bad quality calls (3%)
D1	MUROS AHS 5.9	48.73	9.75	Bad quality calls (3%)

7.2.2.2.4 OSC capacity gains and HW efficiency

Table 7-21 shows the resulting system capacity gains for all MUROS configurations and all channel mode adaptation types. Results show very good capacity gains for OSC in MUROS-2 configuration with the mean gain of 75 % for MUROS-2. In the tight reuse cases (MUROS-1 and MUROS-3) OSC provides good gains for AFS 5.9 codec, no gains for AFS 12.2 and approx. 10% loss for GSM HR and AHS 5.9.

Table 7-21: Summary of OSC network level capacity gains [%]

CMA Type	MUROS-1	MUROS-2	MUROS-3 a)	MUROS-3 b)
A	-11.3 %	103.5 %	-12.7 %	-10.0 %
B	0.5 %	42.0 %	-1.2 %	0.6 %
C	88.6 %	116.6 %	23.3 %	85.3 %
D	-12.8 %	36.7 %	-10.4 %	-14.5 %

HW efficiency results are shown in Figure 7-37.

Whilst for MUROS-2 all channel mode adaptation types benefit in terms of HW efficiency between 37% and 103%, HW efficiency can only be improved for channel mode adaptation type C (AFS 5.9) throughout all network configurations varying between 89% (MUROS-1), 116% (MUROS-2), 23% (MUROS-3a)) and 86% (MUROS-3b)).

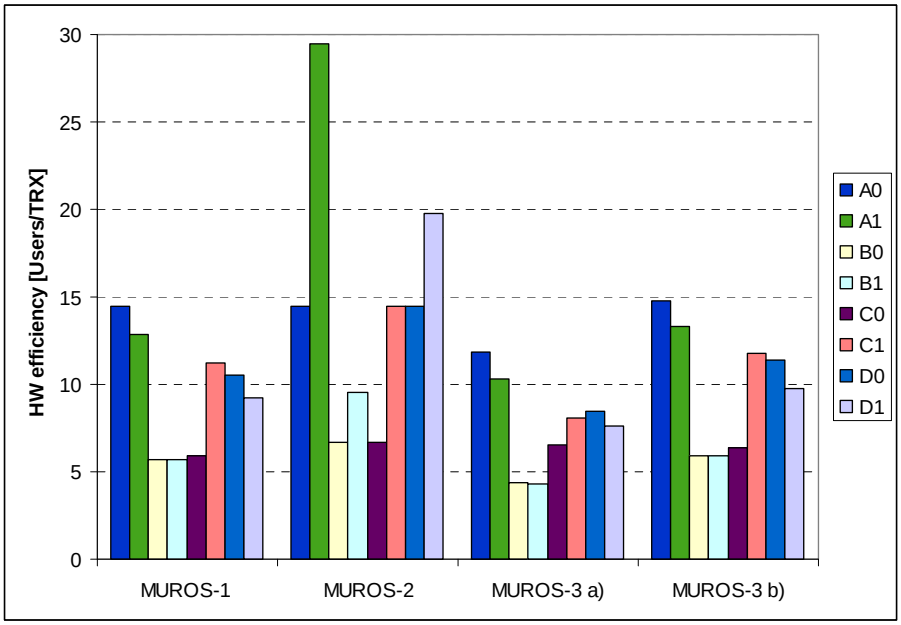

Figure 7-37: HW efficiency for OSC for agreed MUROS network configurations

7.2.2.2.5 Performance of optimized user diversity

Performance was investigated for the proposed optimized user diversity half rate patterns 1, 2 and 3 for network configuration MUROS-1 and channel mode adaptation type D1, i.e. usage of AHS 5.9 codec in legacy channel type and in MUROS channel type. Performance was investigated for different percentages of new OSC aware mobiles (25%, 50%, 75% and 100%). Performance results are depicted in Figure 7-38 and in Table 7-22 below.

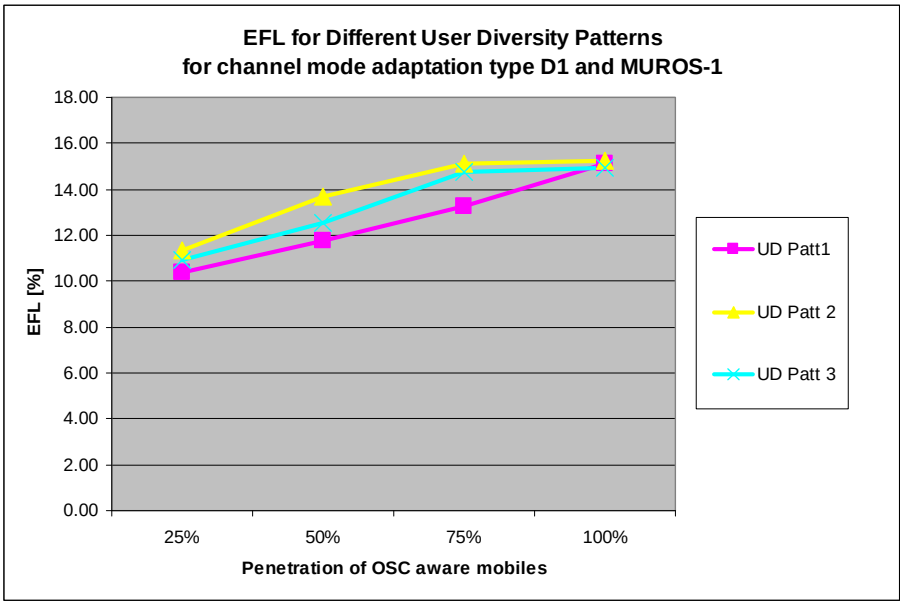

Figure 7-38: EFL for MUROS-1, channel mode adaptation type D1 and different user diversity patterns

Table 7-22: EFL for MUROS-1, channel mode adaptation type D1, different user diversity patterns and different penetration of OSC aware mobiles

Type	25%	50%	75%	100%
UD Patt 1	10.41	11.78	13.23	15.11
UD Patt 2	11.35	13.65	15.09	15.23
UD Patt 3	10.89	12.52	14.75	14.91

It has to be noted that only a mix of legacy DARP phase 1 and new OSC aware mobiles was investigated here. We observe that user diversity pattern 2 reveals the best performance, distributing the interference diversity best among different users. Since the signalling channels were not included in the evaluation, user diversity pattern 3 always performs worse than user diversity pattern 2 due to lower interference diversity for TCH. For network configuration MUROS-1 gains of 16% and 14% compared against user diversity pattern 1 (no user diversity) were largest for penetration rates of 50% and 75% of OSC aware mobiles. Gain for 25% penetration was about 9% and only a gain of 1% was evaluated for 100% penetration case. Hence this analysis indicates that optimized user diversity reveals benefits for a mix of different mobile receiver types in the network.

7.2.3 Performance Summary

Both link level and system level performance evaluation for the candidate technique OSC have revealed a great potential of OSC to increase network capacity up to 100 %.

System performance of the basic OSC candidate technique as presented to GERAN#36 [7-2] was investigated. Both spectral efficiency and hardware efficiency for OSC were investigated based on the refined minimum quality thresholds of 2% for FR channels and 3% for HR channels for average call FER.

Results have identified high capacity gains between 37% and 117% for MUROS-2 for all channel mode adaptation types, whilst for network configurations with tighter reuse, AMR FR 5.9 codec can still improve both spectral efficiency and HW efficiency, nonetheless to a lower extent, i.e. between 23% and 89% for both.

It has to be noted that foreseen enhancements such as subchannel specific power control on DL and the usage of optimized user diversity patterns has not been included so far for all network configurations. It is expected that enhanced OSC will yield a further performance improvement for all network configurations both for the case of 100% of DARP phase I mobiles and for the case of a mix of SAIC and legacy mobiles.

In addition system performance optimisation requires further refinements in all RRM procedures to fully support the OSC concept, such as Channel Allocation, AMR Channel Mode Adaptation and AMR Codec Mode Adaptation.

7.3 Impacts on the Mobile Station

Legacy AMR mobiles may be capable to receive sub channel 0, if $\pi/2$ rotation is applied in downlink for QPSK. For second sub channel the MS should be able to support new training sequences in both downlink and uplink. Indeed the receiver may need to apply e.g. pre-filtering type of receiver to remove ISI for orthogonality.

To improve the accuracy of channel estimation the receiver may also use both binary training sequences of sub channels, denoted as 'OSC aware RX', resulting about 0.6 dB gain with QPSK like training sequence, see Figures 7-11 and 7-16.

For sub channel specific PC the MS needs to be coping with unequal power on sub channels. For user diversity the MS needs to support the specified user diversity patterns and the assisted signalling.

For support of an optimised Tx pulse shape on downlink the MS needs to signal its capability to receive it.

7.4 Impacts on the BSS

7.4.1 BTS Transmitter

The BTS transmitter should support QPSK or QPSK as subset of higher order modulation. Also the symbol rotation of $\pi/2$ needs to be supported by the BTS.

For sub channel specific PC the BTS needs to be able to change mapping of users to 8PSK constellation based on power control indication.

The Tx pulse shaping filter should also facilitate spectrally wider e.g. RRC pulse shape e.g. with 270 kHz bandwidth in order to provide optimised link and system performance. But linearised GMSK may be applied as well assuming that the new pulse shaping filter is optional.

7.4.2 BTS Receiver

The BTS is preferably equipped with 2 receive antennas and uses e.g. either Space Time Interference Rejection Combining (STIRC) or Successive Interference Cancellation (SIC) receiver to receive orthogonal sub channels used by different MSs. Alternatively, the BTS receiver for two GMSK users separated by training sequences could be based e.g. on Joint Detection (JD) of two GMSK users with a JD receiver. A fourth option is to use two independent GMSK receivers for each sub channel.

Indeed BSS should apply uplink power control possibly interworked with Dynamic Channel Allocation (DCA) scheme to keep difference of received uplink signal levels of co-assigned sub channels within e.g. ±15 dB window.

7.4.3 Radio Resource Management (RRM)

The RRM should balance received uplink signal levels of both sub channels within ±15 dB range and should use e.g. current AMR FR or HR traffic channels as a fallback when needed.

With regard to the user diversity procedure, the definition of predefined user diversity patterns as described in the concept section 7.1.2.2.5.3 needs to be undertaken. Thus RRC signalling is needed to indicate during channel assignment the operated user diversity pattern. In addition the sub channel number, the used TSC on this sub channel as well as the new channel type need to be signalled in the channel assignment message.

7.4.3.1 Power Control

Downlink power control may use conditions of the weakest link as criteria. Total power control range for uplink balancing purpose is about 30 dB + 30dB (30 dB range for each multiplexed MS). To make PC four times faster in uplink, Enhanced Power Control may be used.

7.4.3.2 Dynamic Channel Allocation (DCA)

Dynamic channel allocation can sort different OSC voice users to e.g. 30dB windows according to path losses and allocate those to the same resource and balance these further with power control.

Intra Cell Handover for DCA may be triggered for a user having higher or lower level depending on the case. For example a more sensitive user with higher path loss can be left intact, whilst a user with higher level is signalled to perform intra cell HO or vice versa.

7.4.3.3 AMR Channel Rate and Codec Mode Adaptation

The switching between e.g. FR, HR and OSC HR, may use similar criteria as in current FR / HR switching, but may take additionally care about sufficient path loss window to maintain operation of SIC in uplink. AMR Codec Mode Adaptation may rely on current parameters.

7.5 Impacts on Network Planning

7.5.1 Impacts to Abis interface

In order to support OSC, dimensioning aspects on Abis interface have to be considered. In the following impacts on Abis allocation strategy, Abis bandwidth consumption and Abis migration paths are considered in more detail.

7.5.1.1 Impact of OSC on Abis allocation strategy

Introduction of OSC denotes in the context of Abis interface introduction of 2 new transmission modes (in addition to the existing one where 1 radio channel corresponds to 1 Abis sub channel): OSC Full Rate (OSCFR) mode and OSC Half Rate (OSCHR) mode.

As depicted in Figure 7-39, in OSCFR mode it is possible to transmit 2 FR users in a single radio channel which corresponds to simultaneous occupation of 2 Abis sub channels.

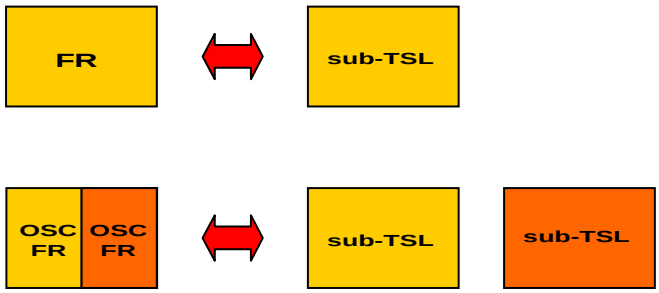

Figure 7-39: Mapping of FR and OSC FR radio channels onto 16 kbit/s Abis sub channels

As depicted in Figure 7-40, in OSCHR mode it is possible to transmit 4 HR users in a single radio channel which also corresponds to simultaneous occupation of 2 Abis sub channels. Note that 2 HR users working in OSC HR mode can also be multiplexed in time. In such case they occupy 1 Abis sub channel (just like 'non OSC' HR call).

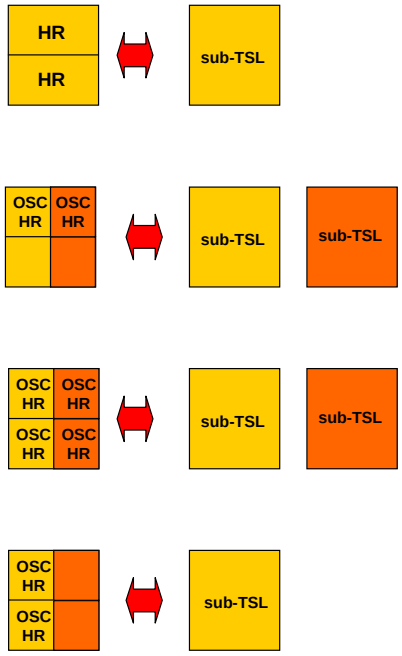

Figure 7-40: Mapping of HR and OSC HR radio channels onto 16 kbit/s Abis sub timeslots

Which of the modes (OSCFR only, OSCHR only or both) is to be used depends on the actual implementation.

7.5.1.2 Impact of OSC on bandwidth consumption

Theoretically, if all Abis timeslots in all TRXs in the given BTS site work at the same time in 'OSC transmission mode' – the Abis bandwidth that would need to be available for CS traffic must be doubled in comparison to 'no OSC transmission mode'. Note that Abis bandwidth reserved for signalling must also be adjusted accordingly in such case.

However, unless a 100% penetration of OSC capable mobiles is available in the network, it is unlikely to achieve 100% penetration of OSC channels. Thus a suitable mix of OSC channels and legacy FR and HR channels has to be assumed for Abis dimensioning, taking into account that the mobiles may require OSC channel mode adaptation from OSC HR channel mode or legacy HR channel mode to legacy FR channel mode in case of degrading radio conditions. Hence the actual impact of OSC on the Abis interface depends on penetration of the functionality, i.e. the percentage of radio channels working in 'OSC transmission mode'. The greater the penetration of OSC channels the more Abis resources must be reserved for CS domain.

The Abis impact will be studied further in more detail for selected scenarios based on the agreed network configurations.

7.5.1.3 Abis migration paths

Implementation of OSC extending CS capacity on radio and consequently on Abis interface as well contributes to the steadily growing requirements concerning bandwidth available in the transport network in particular with regard to Abis interface. On the other hand additional transport network capacity in terms of TDM lines leads to increase of OPEX since leased lines costs" need to be taken into account. Thus a viable solution is to migrate the transport networks towards packet based ones and to IP based ones as replacement of the existing TDM-based networks. One of the possible migration strategies is the introduction of pseudowire emulation which allows to convert the selected PCM lines into IP packets and then to transmit their content by means of Ethernet network. This allows to smoothly migrate from TDM-based transport to IP-based one in pace depending on availability of reliable IP/Ethernet networks. Final step consists in using 'native' IP networks to transmit traffic produced in the RAN. With these solutions further OPEX savings in terms of smaller bandwidth consumtion in the transport networks are expected due to additional traffic optimization and statistical multiplexing effects.

7.5.2 Impacts on Frequency Planning

OSC channels can be employed both on BCCH carrier and on TCH carrier. In case of usage of the legacy GMSK pulse shape no straight impact on frequency planning is observed. All proposed techniques, such as subchannel specific PC, power balancing, usage of new TSC"s and user diversity are operating independent of used frequency hopping scheme. However as performance investigations have shown, OSC can exhibit best performance for HW limited scenarios and loose frequency reuses. For tighter frequency reuses further optimizations of RRM algorithms and application of enhancement techniques need to be executed, before the potential of capacity improvement for OSC can be identified for these scenarios.

Since OSC operates best for loose reuse scenarios, deployment on the BCCH carrier is a viable option. This is also true in case an optimized Tx pulse shape as described in section 7.1.2.1.3 is employed on downlink to minimise ISI. In case an optimized Tx pulse shape is used on the TCH layer, further investigations are required to identify the overall performance gain taking into account impact of the wider pulse on reception of legacy mobiles. Hence this should be studied in the context of an optional enhancement of the OSC feature.

7.6 Impacts on the Specifications

In Table 7-23 a list of affected specifications and the respective subjects for introducing OSC into GERAN is shown.

Table 7-23: Affected existing specifications for OSC

Spec No.	Subject
24.008	Capability indication for OSC solution
	Capability indication for support of optimized pulse shape
44.018	RR support for OSC solution
45.001	Overview of OSC solution
45.002	New training sequences, multiplexing definitions
45.003	Definition of coding required for OSC
45.004	Modulation definition for OSC in downlink
	Specification of an optimized TX pulse shape on downlink
45.005	Test Scenarios for OSC
	Spectral requirements for downlink
	Performance requirements for legacy GMSK pulse shape on DL
	Performance requirements for optimized TX pulse shape on DL
45.008	Link quality control measurements
48.008	Introduction of the signalling for support of OSC
48.058	Introduction of the signalling for support of OSC

7.7 Summary of Evaluation versus Objectives

In this section the candidate technique is evaluated against the defined objectives in chapter 4. Note, this section represents the view of the proponents of this candidate technique.

The following classification is used for the evaluation:

Fulfilled

Expected to be fulfilled

Unclear/FFS

Not fulfilled

7.7.1 Performance objectives

Evaluation of MUROS Candidate Techniques **Performance Objectives**	**Orthogonal Sub Channels**
P1: Capacity Improvements at the BTS 1) increase voice capacity of GERAN in order of a factor of two per BTS transceiver 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Gains have been shown by system level simulations to be between 20% and 76% dependent on the system scenario and speech codec investigated for OSC. Further gains on top have been shown when utilizing sub channel specific power control in the range of 7% to 16% or are expected related to the usage of optimized Tx pulse shape on DL.
	2) All codecs are supported.
P2: Capacity Improvements at the air interface 1) enhance the voice capacity of GERAN by means of multiplexing at least two users simultaneously on the same radio resource both in downlink and in uplink 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Two users are multiplexed on the same radio resource both in uplink and downlink.
	2) All codecs are supported.

7.7.2 Compatibility objectives

Evaluation of MUROS Candidate Techniques Compatibility Objectives	Orthogonal Sub Channels
C1: Maintainance of Voice Quality 1) voice quality should not decrease as perceived by the user. 2) A voice quality level better than for GSM HR should be ensured.	1) It is assumed that channel mode adaptation (CMA) takes place if quality in OSC channel degrades. Also only users with sufficient quality will be multiplexed on the OSC channel.
	2) Minimum FER thresholds have been defined in the TR, and these have been taken into account in system level analysis.
C2: Support of Legacy Mobile Stations 1) Support of legacy MS w/o implementation impact. 2) First priority on support of legacy DARP phase 1 terminals, second priority on support of legacy GMSK terminals not supporting DARP phase 1.	1) Link level performance for a mix of SAIC and non-SAIC mobiles were shown at GERAN#39. Results from other vendors do confirm results from Nokia Siemens Networks.
	2) System level performance for 100 % DARP phase 1 mobiles were shown at GERAN#39, inclusion of legacy non-SAIC MS were studied in based on usage of subchannel specific power control.
C3: Implementation Impacts to new MS's 1) change MS hardware as little as possible. 2) Additional complexity in terms of processing power and memory should be kept to a minimum.	1) Basic SAIC implementation would be sufficient to support the proposal. Only the knowledge of new TSCs is needed.
	2) For new MS the only additional requirement is the awareness of the new TSCs. Power control in downlink is expected to be transparent to the MS implementation. No additional functionality is needed to support OSC except for SAIC capabilities.
C4: Implementation Impacts to BSS 1) Change BSS hardware as little as possible and HW upgrades to the BSS should be avoided. 2) Any TRX hardware capable for MUROS shall support legacy non-SAIC mobiles and SAIC mobiles. 3) Impacts to dimensioning of resources on Abis interface shall be minimised.	1) No BTS HW change required, since QPSK and 8-PSK are supported on EDGE capable BTS. JD or SIC receiver with IRC needed.
	2) For EDGE capable BTS this is usually the case.
	3) Impact is to reserve a higher number of sub channels on Abis interface and possibly use another packet Abis technology.
C5: Impacts to Network Planning 1) Impacts to network planning and frequency reuse shall be minimised. 2) Impacts to legacy MS interfered on downlink by the MUROS candidate technique should be avoided in case of usage of a wider transmit pulse shape on downlink. 3) Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator"s band allocation and in country border regions where no frequency coordination are in place.	1) No impact on frequency planning or frequency re-use is foreseen.
	2) Impacts on legacy MS reception for optimised TX pulse shape need to be further investigated.
	3) Optimised TX pulse shape is not expected to be used at band edge or at the edge of an operator's allocation.

OSC is believed to have a high potential for voice capacity improvement, as has been shown in this chapter of the TR. Investigations on OSC have confirm the high potential for doubled voice capacity in GERAN networks depending on the frequency reuse of the network under interest. Furthermore a solution by applying subchannel specific power control has been created to allow for efficient multiplexing including legacy mobiles. Further enhancements using new user diversity have been defined to improve interference diversity for traffic channels but also for SACCH control channels. Considering that an urgent need for this improvement has been expressed in particular by asian operators [7-9], it is believed that GERAN should agree to open a work item on the introduction of orthogonal sub channels.

8 Adaptive symbol constellation

8.1 Concept Description

In the uplink the MS shall use GMSK modulation. A different training sequence shall be assigned to each MS. The BSS shall implement a multi-user multiple-input-multiple-output (MU-MIMO) receiver in order to decode the two desired signals.

In the downlink, a linear modulator using a rotating hybrid quaternary complex symbol constellation is proposed. The modulation is adaptive since the signal constellation may be time dependent. The constellation can be chosen according to the capabilities or radio conditions of the MS"s. Two sub-channels are created from the real and imaginary parts of the baseband signal. Legacy GMSK MS may be assigned one of the subchannels provided a legacy training sequence is used.

A new set of training sequences with good orthogonality properties shall be designed in order to optimize the link performance both in the uplink and the downlink.

8.1.1 Symbol Constellation for the Downlink

A parameter $0 \le \alpha \le \sqrt{2}$ is chosen to create a quaternary constellation as shown in Table 8-1.

$\alpha\sqrt{\frac{1}{2}} + j\sqrt{2-\alpha^2}\sqrt{\frac{1}{2}}$	$\alpha\sqrt{\frac{1}{2}} - j\sqrt{2-\alpha^2}\sqrt{\frac{1}{2}}$	$-\alpha\sqrt{\frac{1}{2}} + j\sqrt{2-\alpha^2}\sqrt{\frac{1}{2}}$	$-\alpha\sqrt{\frac{1}{2}} - j\sqrt{2-\alpha^2}\sqrt{\frac{1}{2}}$

Table 8-1 α -QPSK Constellation

The constellation of Table 8-1 shall be called an α *-QPSK constellation.* The extreme values α = 0 and $\alpha = \sqrt{2}$ yield BPSK constellations, while for α = 1 an ordinary QPSK constellation is obtained. Figure 8-1 depicts the case α = 0.6.

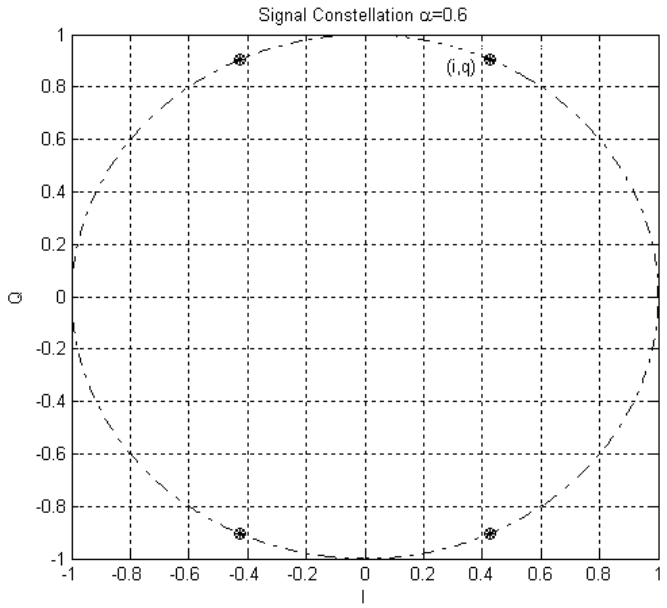

Figure 8-1: Example α -QPSK constellation

As α changes the power in the *I* channel is changed by $10\log_{10}(\alpha^2)$ dB, relative to the power of the *I* channel when using ordinary QPSK. Similarly, the power in the *Q* branch is changed by $10\log_{10}(2-\alpha^2)$ dB relative to the power of the *Q* branch for ordinary QPSK. The cross power ratio χ, depicted in Figure 8-2, between the *I* and *Q* branches is determined by α as:

$$\chi = 10\log_{10}(\frac{\alpha^2}{2-\alpha^2})$$

It is expected that legacy GMSK mobiles will be able to demodulate one of the sub-channels, provided α is chosen so that $|\chi|$ is large enough. This assumption is verified in section 8.2.1.3.1 .

Note that the energy in an α -QPSK constellation is always 1, independent of α.

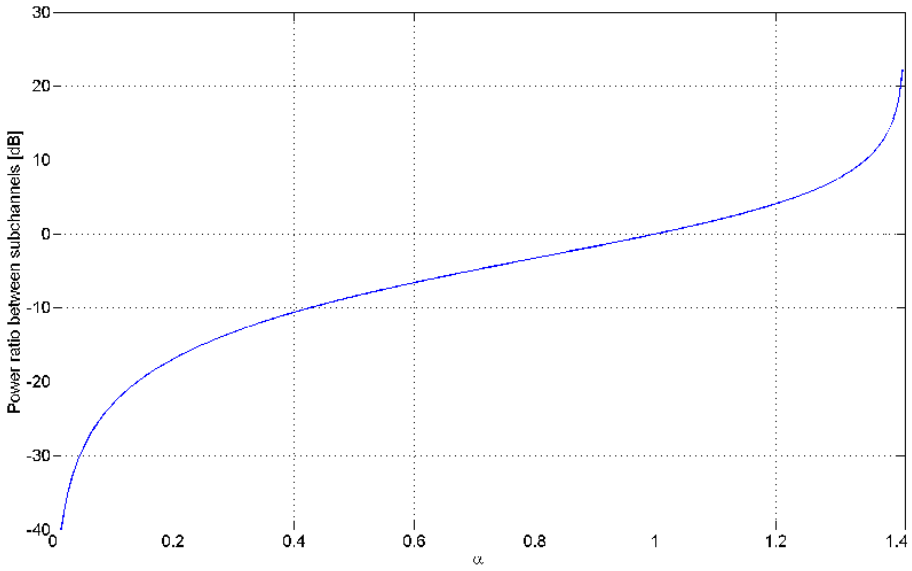

Figure 8-2: Cross power ratio

8.1.2 α-QPSK Modulator

The linear modulator required to create the hybrid quaternary symbol constellation of Table 8-1 is depicted in Figure 8-3. The code bits are modulated to binary symbols {-1,+1}. This results in two binary symbol streams a_n and b_n that are mapped to one α -QPSK symbol stream c_n. The quaternary symbol stream is rotated and passed through a linear pulse shaping filter. Finally the signal is up-mixed to the carrier frequency and amplified.

The two users are separated by means of different training sequences. The use of orthogonal training sequences will improve the performance. Utilizing a pulse shaping filter that satisfies the Nyquist criterion will maintain the orthogonality of the *I* and *Q* sub-channels. The legacy linearized GMSK pulse may be used in order to comply with the legacy spectral mask.

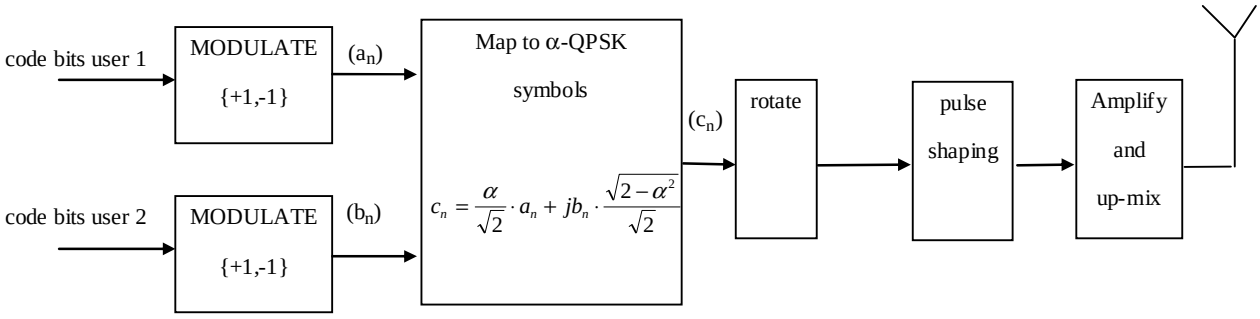

Figure 8-3: α -QPSK modulator and transmitter

8.1.3 Choice of Symbol Constellation

To determine symbol constellation, i.e. α , the modulator may receive feedback from the MS"s. For example α may depend upon the reported RXQUAL, or upon the capabilities of the MS"s, e.g. legacy/legacy SAIC/α -QPSK-aware. This process is illustrated in Figure 8-4, where the box labeled α -QPSK modulator contains the modulator described in Figure 8-3. The BSC box represents the Base Station Controller.

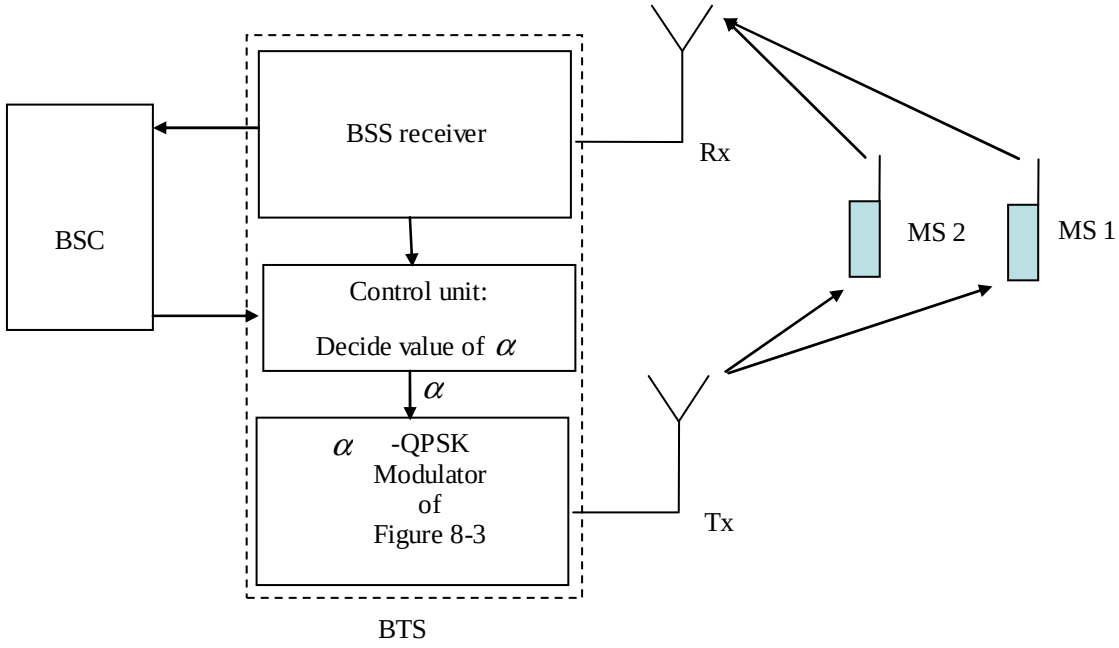

Figure 8-4: Adaptive α -QPSK modulator

The BSS decides the powers P1 and P2 required for MS1 and MS2 respectively, depending on the reported capabilities, RXQUAL and RXLEV by each MS. The control unit computes a combination of output power P and α that gives the required combination of P1 and P2. Dynamic Channel Allocation (DCA) may be used to move users from shared radio resources to not shared radio resources and vice versa.

An α -QPSK-aware mobile may ignore the value of α . However, it can be advantageous to use it during the demodulation process. Depending on the algorithm used at the control unit, an α -QPSK-aware MS may not have knowledge of the value of α used by the modulator in the BTS. If it is unknown then it can be estimated. In section 8.2.1.2.2 simulations are presented to show that the estimation is feasible.

8.1.4 Adaptive Constellation Rotation

Since compatibility with legacy mobiles is desired, it has been proposed to rotate the signal by $\pi/2$. However, this rotation angle is not optimum in terms of PAR for these symbol constellations. Typical power amplifiers are peak limited, which for a signal with high PAR requires additional power backoff. Hence, as the PAR increases, the coverage of the BTS decreases.

To optimize PAR in the DL it is proposed to adapt the rotation angle to the capabilities of the MS receivers. The penetration of MUROS MSs will increase with time. Eventually two MUROS mobiles will be assigned to two orthogonal sub-channels. In this case, there"s no need to continue using the sub-optimal rotation angle. For example, if QPSK modulation is used, then rotation by $\pi/4$ will result in lower PAR and will eliminate zero crossings. The figures below illustrate this fact. The unit circle is depicted in red and the baseband signal in blue.

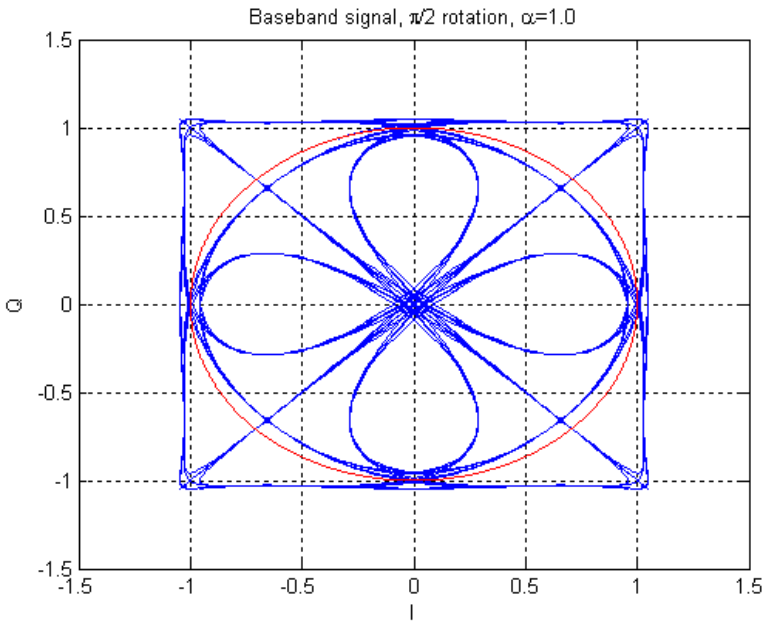

Figure 8-5: Example baseband signal. Ordinary QPSK. $\pi/2$ rotation. Linearized GMSK Tx pulse

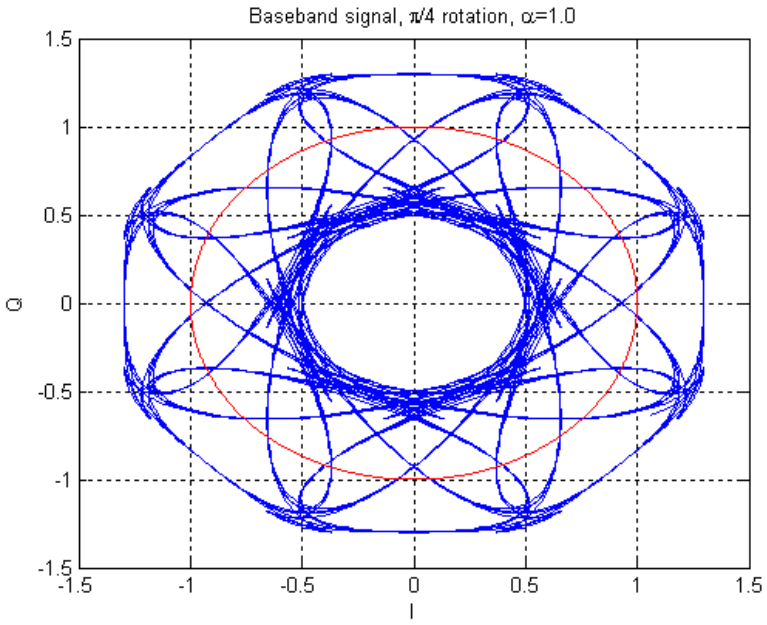

Figure 8-6: Example baseband signal. Ordinary QPSK. $\pi/4$ rotation. Linearized GMSK Tx pulse

The rotation angle shall be chosen so that PAR is minimized. If there is a legacy mobile in at least one of the sub-channels then the BTS modulator rotates the signal by $\pi/2$. However, if two α -QPSK MUROS mobiles are paired together on orthogonal sub-channels, the transmitting base station can choose constellation rotation to minimize PAR. To illustrate the concept Figure 8-7 shows the PAR as a function of alpha for α -QPSK constellations rotated л/2 and л/4 radians.

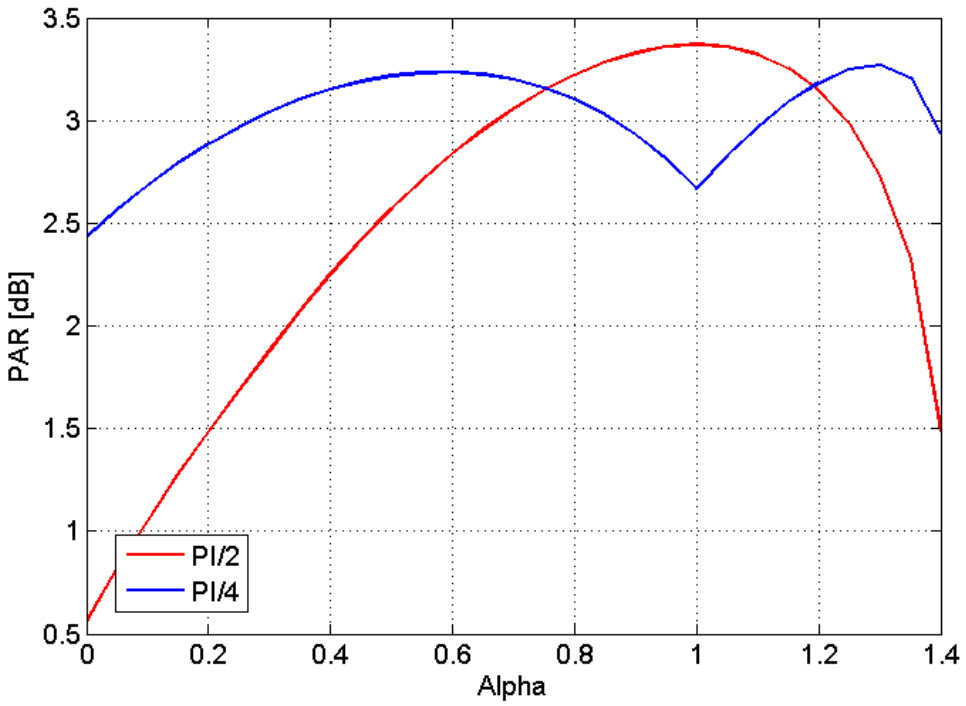

Figure 8-7: PAR as a function of alpha

When alpha equals 0.77 and 1.19 the two PAR curves intersect. To minimize the signal PAR a base station would hence adapt its choice of rotation according to the active alpha value:

$$rot(\alpha) = \begin{cases} \pi/4, & \text{if } (0.77 < \alpha < 1.19) \\ \pi/2 & \text{otherwise.} \end{cases}$$

On the receiver side, the MS performs blind detection of the rotation angle, among a predetermined set of rotation angles. From EGPRS it is known that blind detection of rotation is possible with negligible performance loss and low computational complexity. This assumption is verified in section 8.2.1.2.2.2.

8.1.5 Frequency hopping

Since the intra-cell interference is vastly increased by the introduction of multiple users re-using the same time slot it has been considered to increase diversity (i.e., to ensure that a user is not continuously interfered by the same other user). Diversity is achieved by means of frequency hopping. The frequency hopping schemes can be applied both in the uplink and downlink. Initial simulations in the downlink show substantial gains. The performance in the UL is FFS.

Assume that the MAIO takes values in the set $\{0,1,\ldots,N-1\}$. Denote by S_N the symmetric group on the set $\{0,1,\ldots,N-1\}$. S_N consists of all bijective mappings from $\{0,1,\ldots,N-1\}$ to $\{0,1,\ldots,N-1\}$. In other words, an element $\sigma \in S_N$ is a permutation of the set of N integers $\{0,1,\ldots,N-1\}$. The length of the MAIO hopping sequence is chosen to be an arbitrary positive integer M. A MAIO hopping sequence is defined by a set of M elements $\sigma_0,\ldots,\sigma_{M-1}$ of S_N. Repetitions are allowed. That is, it is possible to choose $\sigma_m = \sigma_n$ for $m \neq n$. Given a time specified by the counter FN, the MAIO for the i-th call assigned to the second OSC sub-channel is

$$\text{MAIO}_{\text{FN}}(i) = \sigma_{FN \bmod M}(i),\ 0 \le i \le N-1. \quad (1)$$

Here mod denotes the arithmetic modulo operator.

Since the same hopping sequence is used for the different sub channel sets it is guaranteed that at most two users hop onto the same frequency and timeslot at any time instant.

First the case when available frequency hopping is re-used for MUROS.

Assume that two more mobile stations are present in the cell, M4 and M5. They are assigned parameters as shown in Table 8-2.

Table 8-2: Frequency hopping parameters for case with existing OSC solution

	M1	M2	M3	M4	M5
MA	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}
Basic hopping sequence[5]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]]	[2,3,1,0,2,0,1,3]
MAIO	0	1	2	0	1
Sub-channel	0	0	0	1	1
Frequency sequence	[7,10,4,0,7,0,4,10, …]	[10,0,7,4,10,4,7,…]	[0,4,10,7,0,7,10,4, …]	[7,10,4,0,7,0,4,10, …]	[10,0,7,4,10,4,7, …]

Using the frequency sequence in Table 8-2 results in the frequency hopping illustrated in Figure 8-8. It is evident that mobile stations M1 and M4 continuously use the two sub-channels of the same channel and thereby are subject to each other''s inter-sub-channel interference. Similarly, M2 and M5 continuously interfere each other. M3, on the other hand, is not subject to any inter-sub-channel interference.

5 The length of the hopping sequences are assumed to be eight. These hopping sequences are used for illustrative purposes only and do not reflect actual hopping sequences for GSM [8-4].

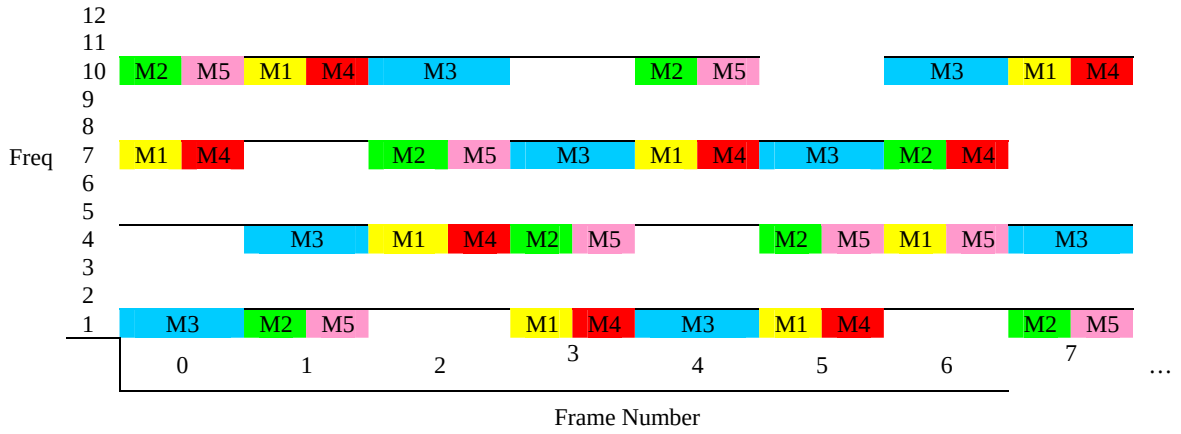

Figure 8-8: Frequency hopping, with existing OSC solution

Finally, consider the OSC solution with improved frequency hopping. Assume there are still 5 mobile stations in the cell (on the considered timeslot number). The same parameters are used as in Table 8-2 but users of the second sub-channel, i.e. M4 and M5 will hop between the MAIOs.

A set of permutations giving the MAIO hopping sequences in Table 8-3 is chosen.

Table 8-3: MAIO Hopping Sequences

	MAIO							
M4	0	2	2	1	2	0	2	1 …
M5	1	1	0	0	1	2	0	0 …
	FN=0	FN=1	FN=2	FN=3	FN=4	FN=5 .	FN=6	FN=7 …

The following table shows the resulting assignment of frequencies.

Table 8-4: Frequency sequences

	M1	M2	M3	M4	M5
MA	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}	{1,4,7,10}
Basic hopping sequence[6]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]	[2,3,1,0,2,0,1,3]
MAIO	0	1	2	from Table 8-3	from Table 8-3
Sub-channel	0	0	0	1	1
Frequency sequence without hopping over MAIOs	[7,10,4,0,7,0,4,10,…]	[10,0,7,4,10,4,7,…]	[7,1,10,4,1,7,10,4,…]	[7,10,4,0,7,0,4,10,…]	[10,0,7,4,10,4,7,…]
Frequency sequence applying cyclic hopping over MAIOs in sub-channel 1	[7,10,4,0,7,0,4,10,…]	[10,0,7,4,10,4,7,…]	[7,1,10,4,1,7,10,4,…]	[7,4,10,4,0,0,10,0 ,…]	[10,0,4,0,10,7,4,10,…]

The resulting frequency hopping is illustrated in Figure 8-9. It can be seen that the interference diversity has improved. E.g., mobile station M1 is sometimes interfered by M4, sometimes by M5 and sometimes not interfered at all. A similar improvement is seen for M2. M3, which was never subject to inter-sub-channel interference with the existing OSC solution, is now sometimes interfered by M4 or M5. But the fairness has improved due to the improved frequency hopping. Further, since the channel coding makes the channel robust to a certain amount of interference, it is likely that the speech quality on average has improved in the cell (assuming the network is well dimensioned to handle the given load). No simulation results have been provided in this document but similar gains as shown in [8-3] can be expected.

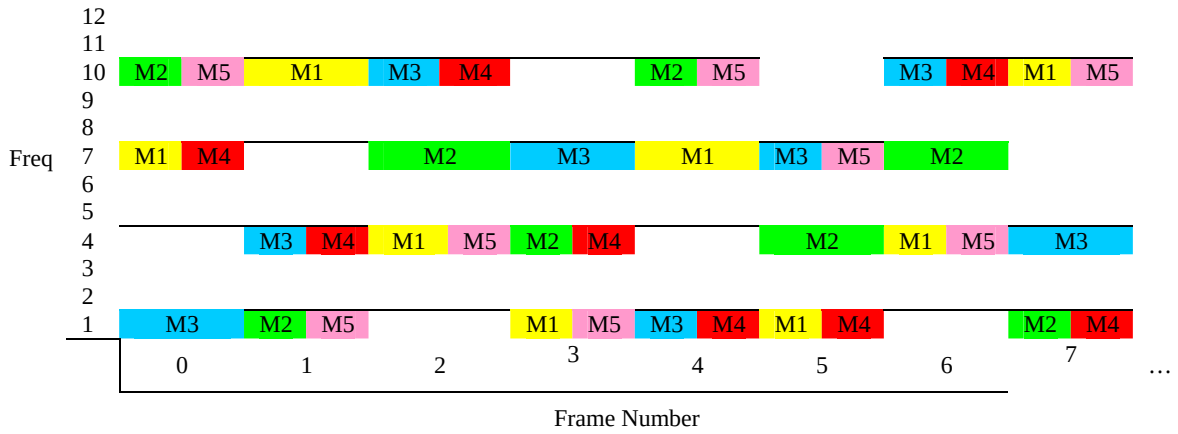

Figure 8-9: OSC with improved frequency hopping

[6] The length of the hopping sequences are assumed to be eight. These hopping sequences are used for illustrative purposes only and do not reflect actual hopping sequences for GSM [8-4].

8.1.5.1 Legacy support

Since the frequency hopping scheme uses already available MAIO hopping the diversity scheme will support legacy mobiles (given that legacy mobiles can be supported by the MUROS concept and that they are allocated to sub channel one). Note that also legacy mobiles will be able to utilize the gain of the frequency hopping feature, especially when having fractionally loaded TSs.

8.1.5.2 Additional signaling

Both the users of the first and second sub-channel will re-use the frequency hopping in GSM is defined in the 3GPP specification 45.002 [8-4]. However, the second set of users will use an additional hopping sequence to hop between MAIOs, which needs to be signaled to the mobile station.

To generate the MAIO hopping sequence, the MS must know the set of allowed MAIOs (the MAIO Allocation, *MAIOA*). Given the MAIOA, the number of MAIOs to hop over is known. Assuming that the permutations are predetermined and stored in the mobile station, the MS selects the permutation corresponding to the size of the MAIOA and an additional parameter determining which MAIO hopping sequence to use (the parameter *I* in the example in section 8.1.5). This is here denoted the *MAIOHSN*.

Optionally, several permutations can be defined for each given MAIOA size. This requires another parameter to be signaled to the mobile station, a MAIO permutation number, MAIOPN.

The MAIOA, the MAIOHSN and optionally the MAIOPN need to be signaled to the mobile station during assignment, handover and reconfiguration. It is necessary to update the relevant signaling messages to convey the new parameters.

Since the resource allocation in the cell can change during a call, it should be possible to change the parameters during a call. Therefore, the signaling messages should also include means for coordinating the change to new hopping parameters between all MS, e.g., a *starting time* after which the new parameters apply.

8.2 Performance Characterization

8.2.1 Link Level Performance

Link level simulations have been performed in propagation conditions TU3iFH, TU50iFH and TU3nFH using speech codecs AFS/12.20, AFS/5.90 and AHS/5.90.

Interference simulations as well as sensitivity simulations have been performed for the both DL and UL. Interference scenarios MTS-1-4 has been used for the evaluation.

Sub channel power imbalance ratios, SCPIRs, of -8, -4, 0, 4, 8 dB has been investigated for the DL and SCPIRs of 0,-5,-10,-15 have been investigated for the UL.

8.2.1.1 Simulation assumptions

In the DL simulations, three different receiver types have been used: non-SAIC receiver, SAIC receiver and MUROS receiver. For the UL a Successive Interference Cancellation, SIC, receiver has been used.

For the sensitivity limited scenarios in DL a backoff of 3.3 dB has been used, based on Figuer 8-7. It should be noted that a smaller backoff could be used for alpha values $\neq 1$.
Common simulations assumptions for UL and DL are listed in Table 8-5 and assumptions specific for DL and UL are listed in Table 8-6 and Table 8-7 respectively.

Table 8-5: Common simulations assumptions

Parameter	Value
Speech codec	TCH/AFS12.2, TCH/AFS5.90, TCH/AHS5.90
Channel profile	Typical Urban (TU)
Terminal speed	3 km/h, 50 km/h
Frequency band	900 MHz
Frequency hopping	Ideal, No
Interference/Noise	MTS-1, MTS-2, MTS-3, MTS-4, Sensitivity

Table 8-6: DL simulation assumptions

Parameter	Value
Antenna diversity	No
Frequency offset external interferers	Normal distribution [Hz] N(50,17)
Backoff	3.3 dB
Receiver type	non-SAIC (reference)
	SAIC The SAIC algorithm used for the receiver utilizes a spatial-temporal Vector Autoregressive (VAR) Model
	MUROS The MUROS receiver has been implemented as a single antenna QPSK receiver. Aware of the TSC of both sub channels
Impairments: – Phase noise – I/Q gain imbalance –I/Q phase imbalance – DC offset – Frequency error – PA model	Tx / Rx 0.8 / 1.0 [degrees (RMS)] 0.1 / 0.2 [dB] 0.2 / 1.5 [degrees] -45 / -40 [dBc] - / 25 [Hz] Yes/ -

Table 8-7: UL simulation assumptions

Parameter	Value
Antenna diversity	Yes
Frequency offset external interferers and paired sub channel	Normal distribution [Hz] N(100,33)
Receiver type	SIC, spatio-temporal IRC
	Legacy GMSK, MRC (reference)
Rx filter - Bandwidth - RRC rolloff	RRC[1] 240 kHz 0.3
Impairments: – Phase noise – I/Q gain imbalance –I/Q phase imbalance – DC offset	Tx / Rx 0.8 / 1.0 [degrees (RMS)] 0.1 / 0.2 [dB] 0.2 / 1.5 [degrees] -45 / -40 [dBc]
Note 1: The 3 dB bandwidth of the RRC filter.	

For the UL the wanted sub-channel is denoted C1, while the paired sub-channel is denoted C2. The two columns in the UL plots show the results of the same simulations. The difference is in the scale of horizontal axis. The total carrier to

interference ratio (C/I, where C=C1+C2) is shown on the left hand side, while the sub-carrier to interference ratio C1/I is depicted on the right hand side.

NOTE: The agreed working assumption is to present plots for (C1+C2)/I.

NOTE: The performance for the UL has been normalized so that the reference receiver reaches 1% FER @ 0 dB.

8.2.1.2 Sensitivity Performance

8.2.1.2.1 SAIC receiver

From the simulations below it can be concluded that:

- The SAIC receiver can handle sub channel power imbalance ratios, SCPIRs, $\geq$ -8 dB.
- The higher the SCPIR, the closer the performance is to a legacy GMSK channel.
- The lower the SCPIR the larger degradation. I.e. the degradation from SCPIR=-4 -> SCPIR=-8 is larger than the degradation from SCPIR=0 -> SCPIR = -4.

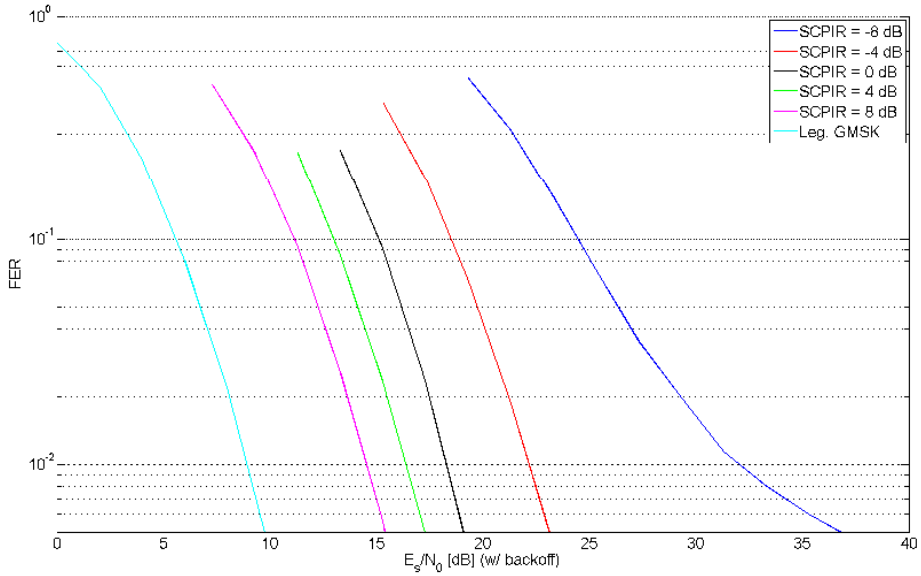

Figure 8-12: AHS/5.90 sensitivity

8.2.1.2.1.1 Support of legacy mobiles

One important objective of the feasibility study is to enable support of legacy mobiles with the new technique. Simulations have been performed by a number of vendors, see [8-5]-[8-9], to investigate the feasibility of using the adaptive symbol constellation concept with legacy SAIC implementations. The simulation results are collected in the following sections. A more detailed description of these findings can be found in [8-10].

It is shown that most SAIC implementations investigated seem to be able to support the concept.

All five references simulated α-QPSK in sensitivity limited scenarios with different speech codecs. AFS12.2 and AFS5.90 was common to all vendors and has thus been used in the comparison.

The different performance has been compared to SCPIR = 0 dB at 10 % FER. Although 1 % FER would be a more suitable measure for speech performance, 10 % has been chosen since more results are available at this level.

In all simulations a TU3iFH channel has been used.

NOTE: The performance shown estimates the performance presented in [8-5]-[8-9].

Based on [8-5]-[8-9] the SNR performance has been estimated at 10 % FER.

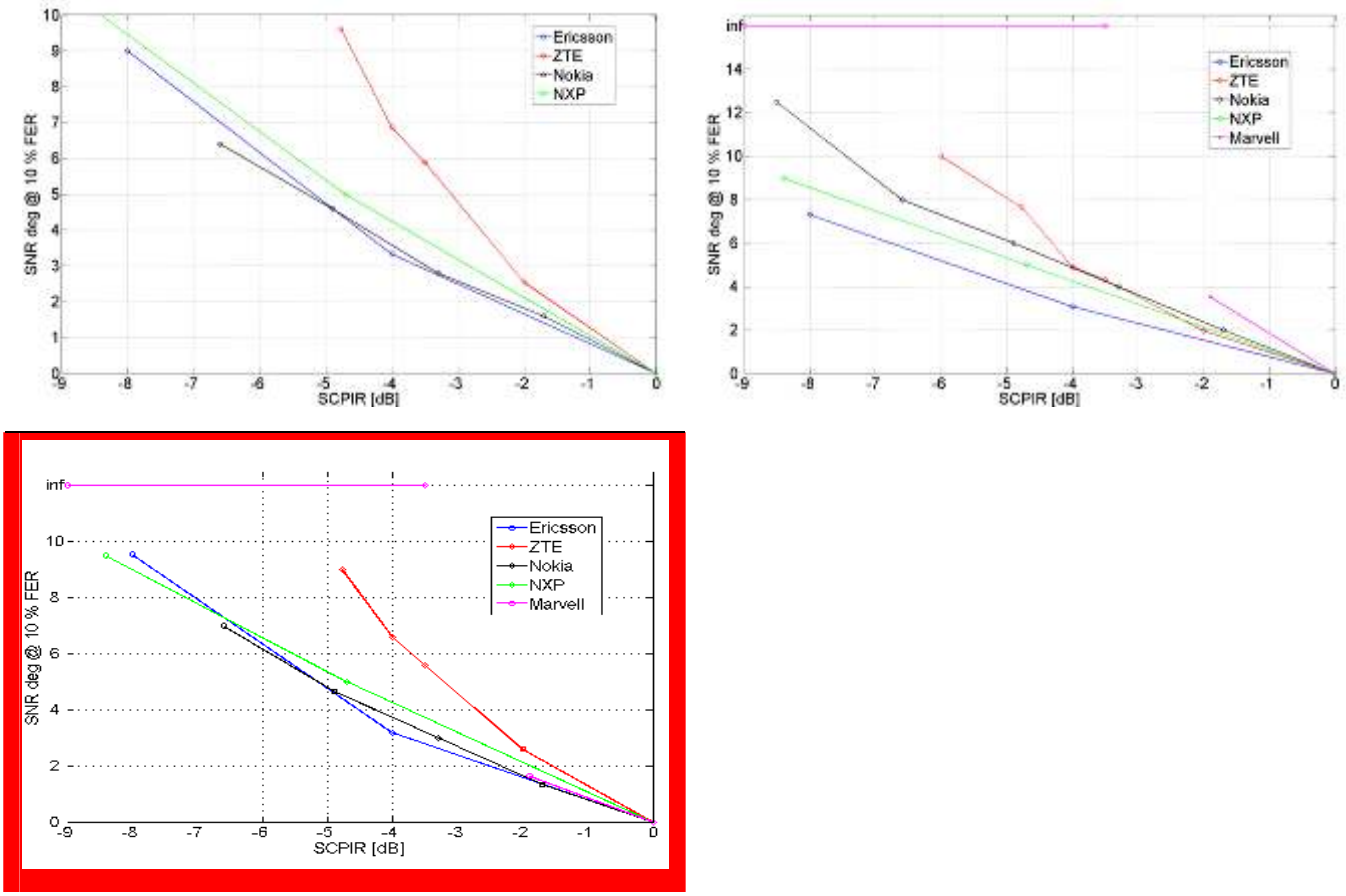

Figure 8-12a: AHS5.9 performance degradation due to SCPIR for AHS 5.90 (top left), AFS 5.90 (top right) and AFS 12.2 (bottom left)

In general it can be seen in Figure 8-12a that most legacy SAIC implementations are aligned in performance (Ericsson, Nokia and NXP) with one implementation giving a larger degradation (ZTE). One SAIC implementation performs significantly different (Marvell), experiencing a FER collapse at SCPIR < -3.5 (Shown in the plot as an infinite performance degradation).

Based on the shown results it seems that most SAIC implementations on the market will be able to support the alpha-QPSK concept. Although there is a difference in performance between vendors, given a certain sub channel power imbalance ratio, it is expected that system functionality, such as, MUROS channel mode adaptation will ensure end user performance not to be degraded.

8.2.1.2.2 MUROS receiver

8.2.1.2.2.1 Symbol Constellation Detection

To illustrate the feasibility of MS symbol constellation detection presented in section 8.1.3 . Figure 8-13 shows the DL performance for scenarios:

- Alpha signaled to the MS, i.e. alpha known by the MS (blue line).
- Alpha estimated with a LS estimator (black line).
- Alpha estimated with a LS estimate smoothed over a measurement period of 480ms (red line).

The performance of the *I* channel is presented. Investigated values of α were selected to make the studied sub-channel both dominant and suppressed, according to Table 8-8.

Table 8-8:Alpha versus relative sub channel power

α	Power ratio [dB]
0.4	-10.6
0.6	-6.6
1.0	0
1.2	4.1

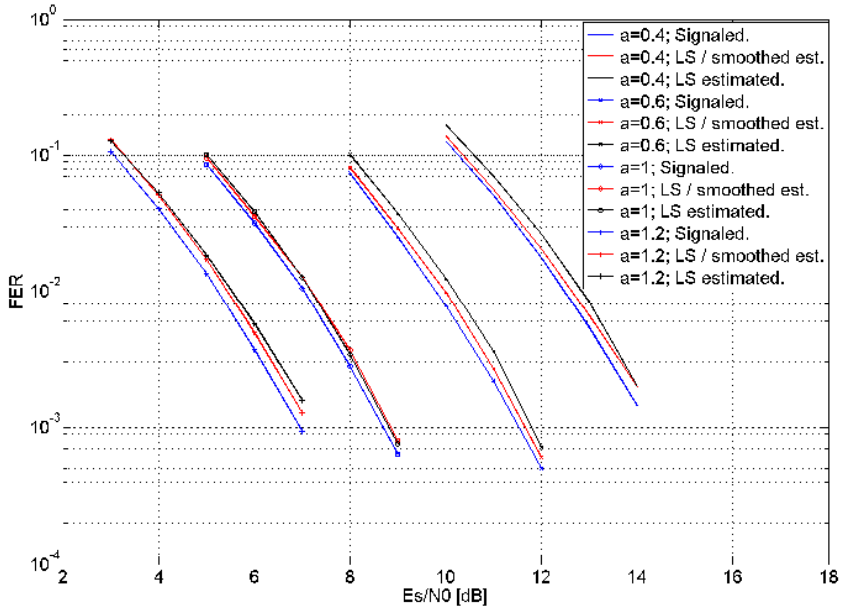

Figure 8-13: AFS5.90 with different receiver information of α

Alpha was restricted to the continuous interval 0.28 - 1.39 to achieve a relative power control range of ±14dB between the two sub channels, as depicted in Figure 8-2. Speech codec AFS 5.90 was utilized during the simulations.

The performance degradation when α is LS estimated and smoothed over a measurement period is below 0.3 dB at all investigated FER levels. When smoothing is discarded the performance is further degraded, but the total degradation never exceeds 0.5dB.

8.2.1.2.2.2 Constellation Rotation Detection

As described in section 8.1.4 when two α -QPSK MUROS mobiles are paired together on orthogonal sub-channels, the BSS can choose the constellation rotation to enhance the PAR.

In order to benefit from the PAR enhancement the MUROS MS"s must be able to detect the constellation rotation. The simulation results presented in Figure 8-14 illustrates the ability of the MS to do so and simultaneous estimate alpha without deteriorating the receiver performance. The results presented were achieved for α -QPSK constellation with a symbol rotation of л/4 and alpha values according to Table 8-9. For each alpha value three scenarios were simulated:

- Alpha value and symbol rotation known by the MS.

- Alpha value estimated while symbol rotation known by the MS.
- Alpha value estimated and symbol rotation detected by the MS.

For alpha equal to 1.0 an additional scenario was simulated:

- Alpha value known while symbol rotation detected by the MS.

In this scenario the α -QPSK MUROS constellation takes the form of a QPSK constellation. This is of relevance since it investigates if the adaptive constellation rotation concept is applicable when MUROS is based on a pure QPSK constellation. Speech codec AFS 5.90 was utilized during the simulations.

Table 8-9: Alpha versus relative subchannel power

α	Power ratio [dB]
0.8	-3.3
1.0	0
1.15	2.9

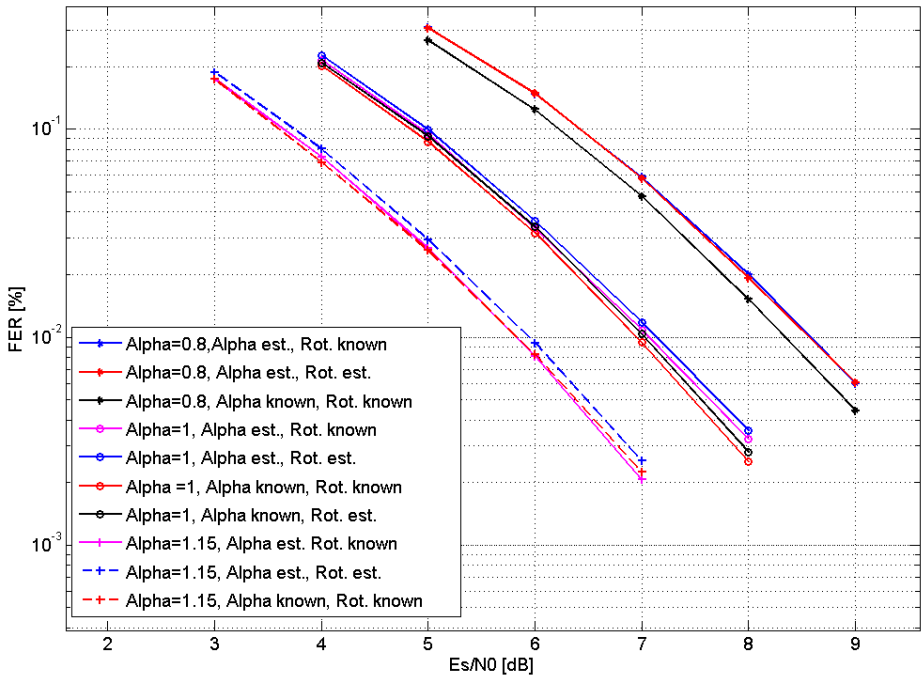

Figure 8-14: MUROS receiver with/without alpha estimation and rotation detection

The receiver performance is dependent on the alpha value. The dominant sub-channel is as expected showing better performance than the suppressed sub-channel. The alpha estimation and rotation detection scenarios are showing a performance degradation of approximately 0.2dB or less compared to the scenarios where both alpha and rotation is known. The same is true when compared to the scenarios where alpha is estimated and rotation is known.

As the degradation due to alpha estimation and rotation detection never exceeds 0.2 dB for any of the studied alpha values it will be compensated by the PAR enhancement presented in Figure 8-7.

8.2.1.2.3 SIC receiver

From the simulations below it can be concluded that:

- In general there is little difference in performance (for both reference and SIC) between the cases with MS speed of 3 km/h and 50 km/h

- In all test cases the performance of the weakest sub-channel is inferior to the performance of the reference MRC receiver at 1% FER.
- The degradation in terms of C1/N at SCPIR > -10 dB is about 2 dB for the AFS 5.9 codec @ 1% FER. For AHS 5.9 the degradation is around 5 dB.

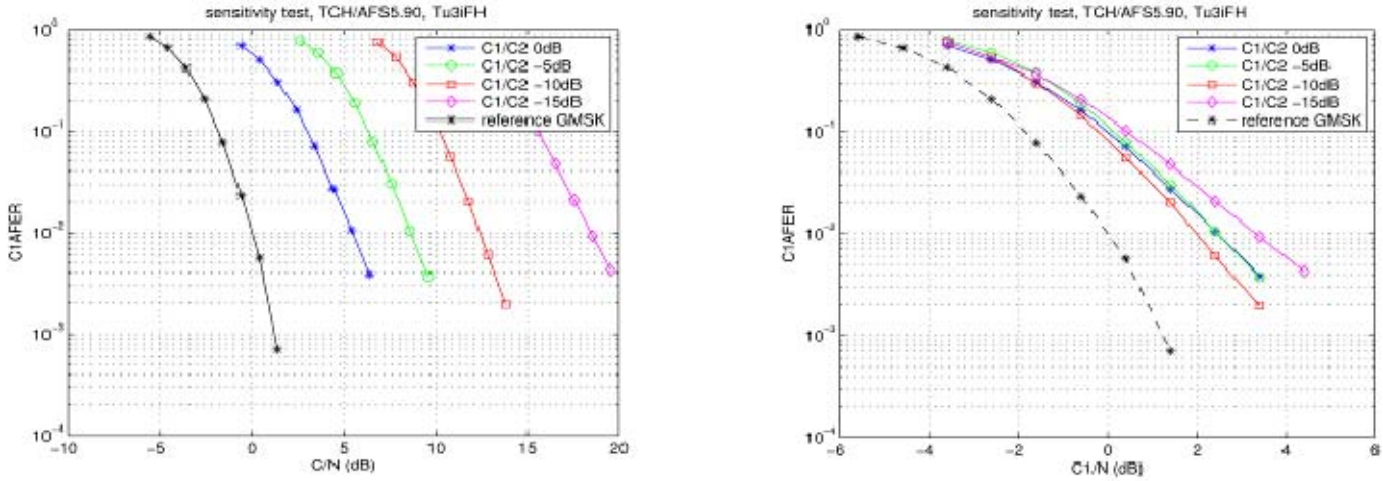

Figure 8-15: Sensitivity, AFS5.90, Tu3iFH

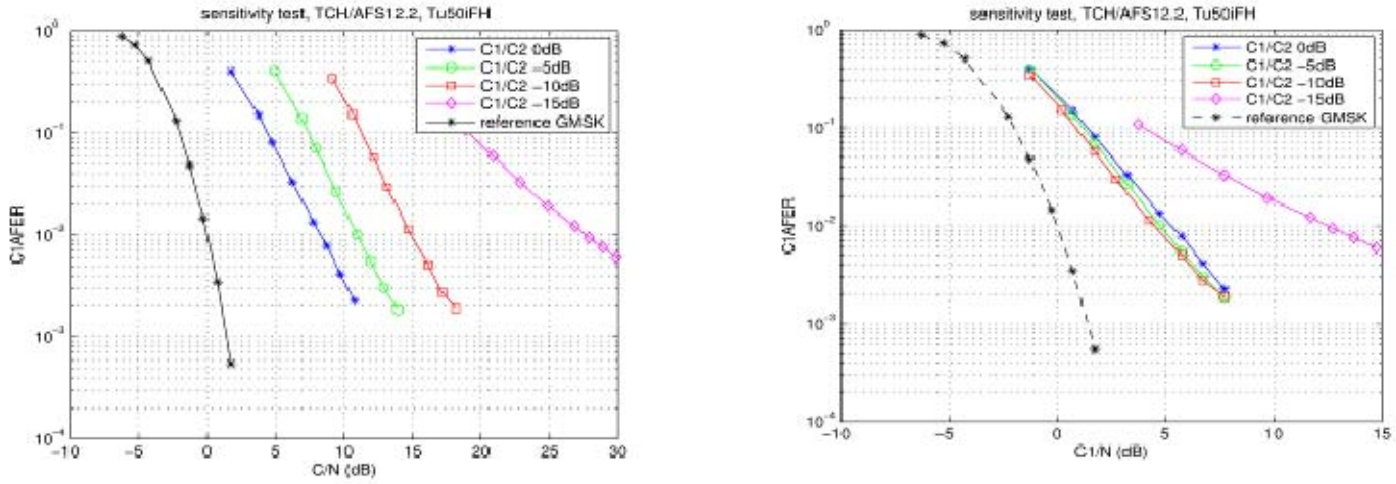

Figure 8-20: Sensitivity, AFS12.2, Tu50iFH

8.2.1.3 Interference Performance

8.2.1.3.1 non-SAIC receiver

The non-SAIC legacy GMSK receiver uses a five tap least squares channel estimate. The α -QPSK-aware receiver uses a quaternary trellis MLSE and α is assumed to be known. The modulator is as described in Figure 8-3. The x-axis has been normalized so that the reference GMSK reaches 1% FER @ C/I = 0 dB. The legacy and α -QPSK-aware receiver use orthogonal training sequences consisting of the legacy TSC0 and the corresponding new sequence from [8-2]. Figure 8-21 shows the performance of the OSC concept as described in [8-2]. The Tx filter is a Hanning windowed RRC, rolloff 0.3, with a 3 dB bandwidth (before windowing) of 270 kHz. Speech codec AMR/HR 7.40 was used.

It is seen that even a robust legacy MS is unusable. In fact the FER for the legacy mobile is never lower than 60%, independently of the C/I.

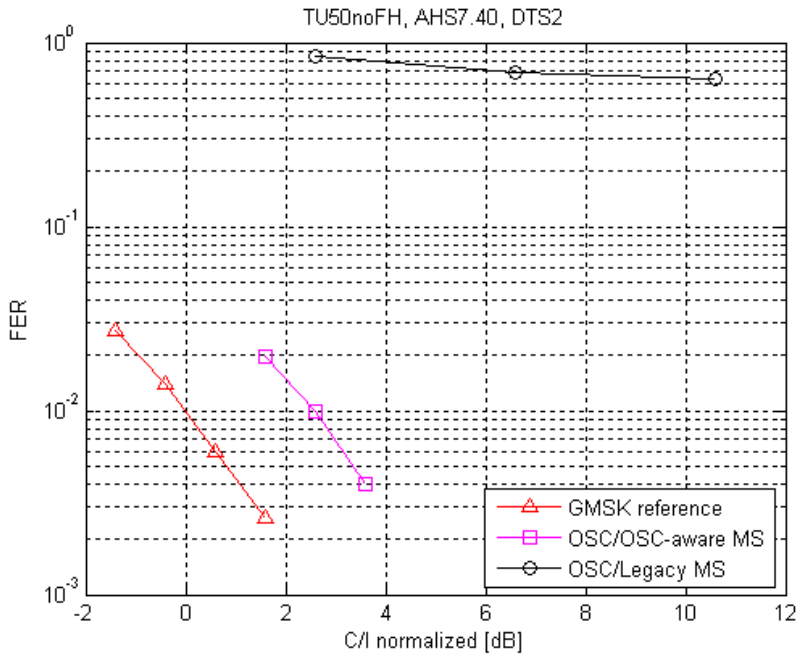

Figure 8-21: OSC with a legacy GMSK receiver in one sub-channel and OSC-aware receiver in the other sub-channel. Wide Tx Pulse

Figure 8-22 shows the performance of α -QPSK modulation. The value of α =0.67 has been chosen empirically, and is assumed to be known at the α -QPSK-aware receiver. The simulation settings used are the same as used in Figure 8-21.

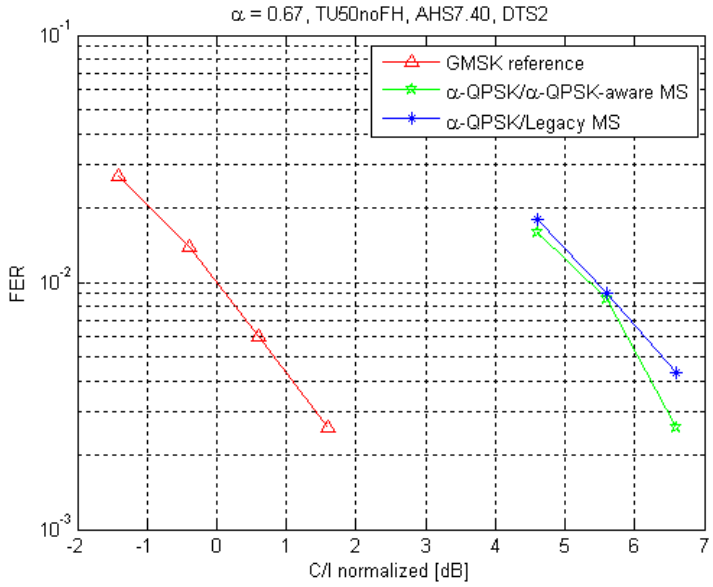

Figure 8-22: α -QPSK modulation with a legacy GMSK receiver in one sub-channel and α -QPSK – aware receiver in the other sub-channel. Wide Tx Pulse

Figure 8-23 shows the performance of α -QPSK-aware and legacy receivers when α =0.67 and the Tx pulse is the linearized GMSK pulse used in EGPRS. The performance is somewhat degraded with respect to the wide Tx pulse performance shown in Figure 8-22.

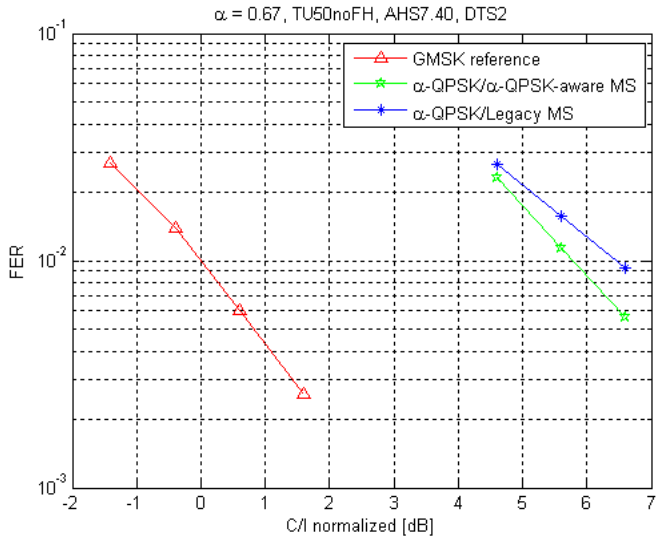

Figure 8-23: α -QPSK modulation with a legacy GMSK receiver in one sub-channel and α -QPSK – aware receiver in the other sub-channel. Linearized GMSK Tx Pulse

Figure 8-24 shows that even two legacy MS"s can be multiplexed using α -QPSK, as long as one of them has a SAIC receiver. The legacy training sequences TSC0 and TSC3 have been used. Recall that the legacy training sequences are not mutually orthogonal. The value α =0.67 has been used even though it is not optimal, because it is instructive to make comparisons with Figure 8-22 and Figure 8-23.

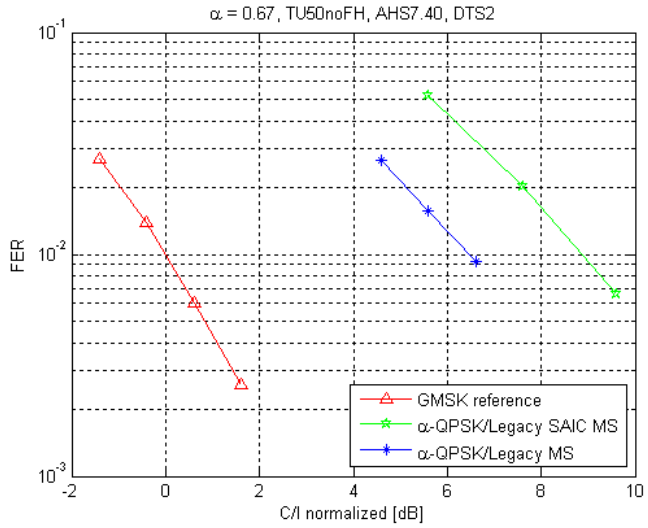

Figure 8-24: QPSK modulation with legacy GMSK receiver in one sub-channel and legacy SAIC GMSK receiver the other sub-channel. The sub-channel decoded by the Legacy SAIC MS has less power than the other sub-channel. Linearized GMSK Tx Pulse

8.2.1.3.2 SAIC receiver

From the simulations it can be concluded that:

- The degradation when changing from GMSK modulation to QPSK modulation of the interferer will be larger, the higher the SCPIR since the SAIC algorithm can suppress the external interferers more efficiently when the other sub channel give rise to less interference. This effect is much more evident in the single interferer scenarios, i.e. MTS-1 and MTS-3.

- In general, the lower the SCPIR the larger degradation. I.e. the degradation from SCPIR=-4 -> SCPIR=-8 is larger than the degradation from SCPIR=0 -> SCPIR = -4.

- For TU3 without frequency hopping a FER of 1 % is not met for AHS5.90 using a SCPIR of -8 dB.

8.2.1.3.2.1 Adaptive Constellation Rotation

Altering alpha or switching the rotation of the α -QPSK MUROS constellation between л/2 and л/4 could deteriorate SAIC mobiles" ability to cancel interference caused by MUROS signals. To investigate this, simulations were conducted for both GMSK and α-QPSK modulated carriers exposed to α -QPSK modulated interference with varying alpha and a rotation of л/2 or л/4 as can be seen in the figure below.

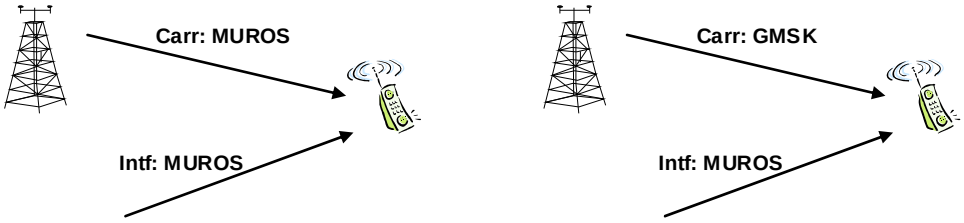

Figure 8-41: Identified interference scenarios

For the α-QPSK modulated carriers the alpha values were chosen according to Table 8-10. The same α-value was used by the carrier and interfering signal. The alpha values and constellation rotations used were chosen from Figure 8-9. Alpha equal to 0.77 and 1.19 represents the extreme values where the rotation switches from π/2 to π/4. As alpha approaches these values the α -QPSK modulation approaches a GMSK constellation.

Figure 8-42 presents the results from the simulation when the carrier was α-QPSK modulated and the interferer either GMSK or α-QPSK modulated. The α-QPSK interferers were rotated л/2 or л/4 while the carrier used a rotation of л/2. The performance degradation due to the change in rotation reaches its maximal value 0.2 dB when α equals 0.77.

Table 8-10: Alpha versus relative sub channel power

α	SCPIR [dB]
0.77	-3.8
0.89	-1.8
1.19	3.8

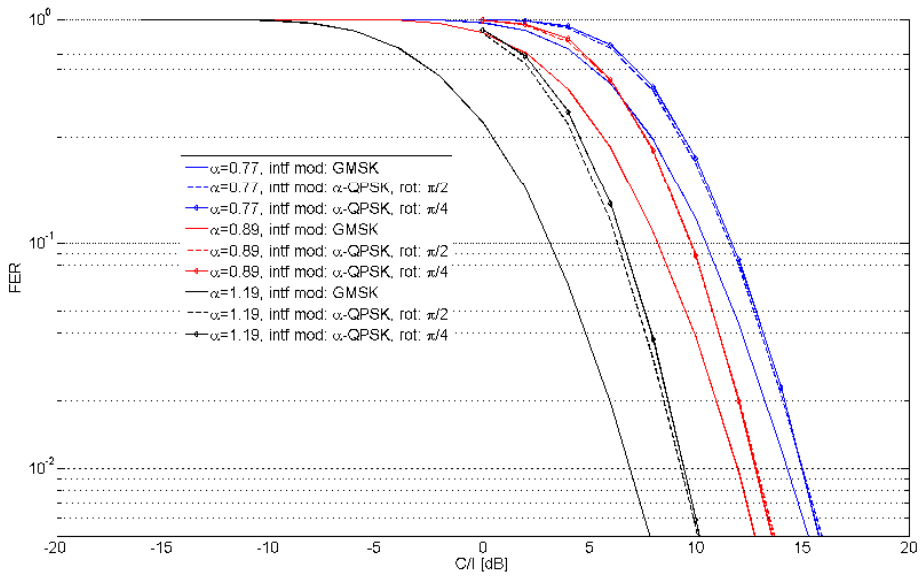

Figure 8-42: SAIC performance when an α-QPSK carrier, using AFS/12.2, is exposed to α-QPSK or GMSK modulated interference

For the scenario when the carrier is GMSK modulated a more thorough investigation was performed. Figure 8-43 shows the SAIC performance when a GMSK carrier is exposed to MTS-1 or MTS-2 interference. The interferers are α-QPSK modulated, and the performance is shown for alpha in the range 0.77 to 1.19, which corresponds to a SCPIR of -3.8 to +3.8dB. For each alpha the symbol rotation of the interferers is л/2 or л/4.

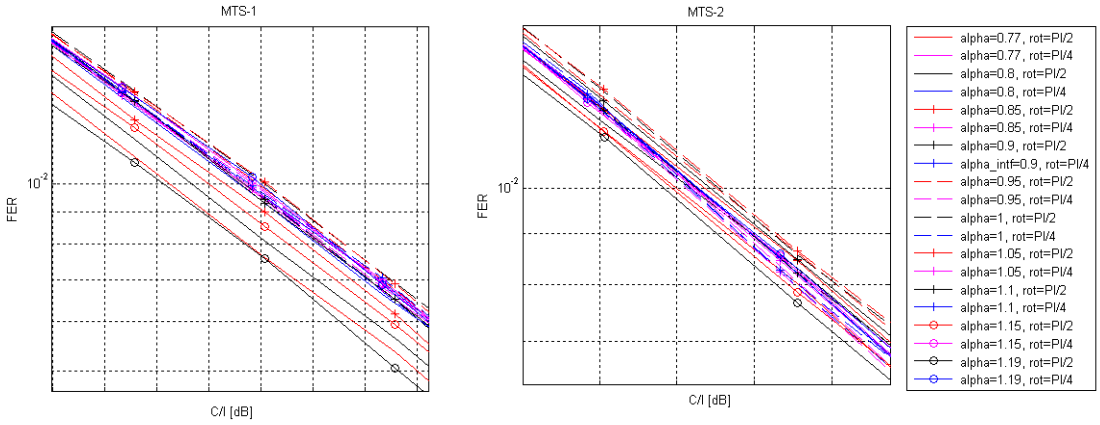

Figure 8-43: SAIC performance for a GMSK carrier when exposed to MTS-1 (left) and MTS-2 (right) interference, where the interferers are alpha-QPSK modulated. Each tick on the x-axis equals 0.2dB

By comparing the performance at the different rotations, it is possible to estimate the performance degradation in dB of the SAIC receiver at 1% FER. Figure 8-44 summarizes this degradation over the studied alpha range. The fine resolution on the y-axis is justified since 150 000 frames per point were simulated. The degradation worsens as alpha approaches the theoretical rotation adaptation thresholds of 0.77 and 1.19. For MTS-1 the maximal degradation equals 0.37dB while 0.09 dB for MTS-2.

It can be seen that when the MS experiences a multiple interferer scenario, the degradation due to the modulation rotation is decreased significantly compared to the single interferer case. It should be noted that the MTS-2 multi-interferer case is seen as the relevant system scenario for MUROS.

Figure 8-44 shows, for both scenarios, that symbol rotation л/4 is preferred when alpha is close to 1. The reason is that when the interferer modulation constellation is QPSK-like the SAIC receiver has limited, or no, capability to suppress the interference, as can also be seen in [8-12] and [8-13], since the two sub channels are always 90 degree phase shifted. On the other hand, л/4 rotation is used in the transmitter and л/2 de-rotation is used in the receiver, resulting in a net rotation of -л/4 for the interference. This type of interference causes less performance degradation in the receiver than a BPSK signal rotated л/2. This resembles the case in EGPRS where it is observed that 8PSK interference is less harmful than GMSK interference for a non-SAIC receiver.

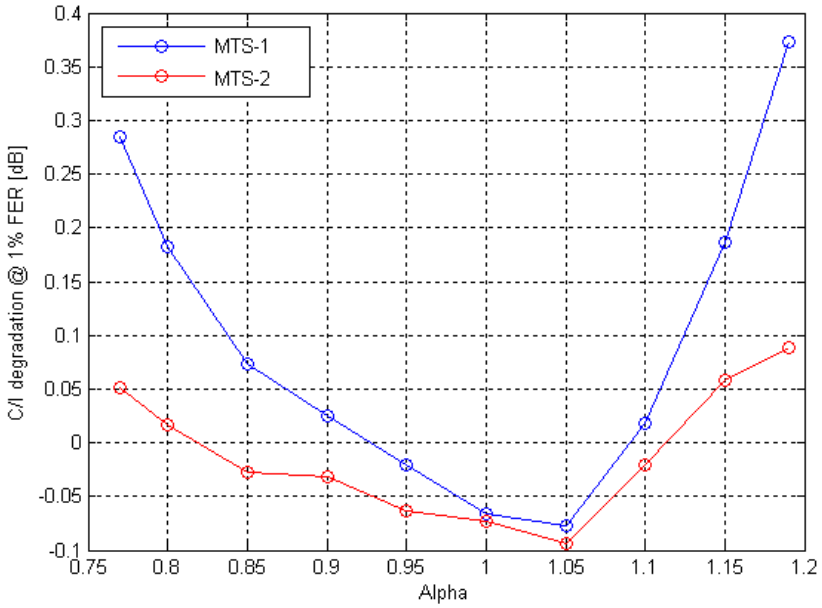

Figure 8-44: C/I degradation at 1% FER

8.2.1.3.3 MUROS receiver

8.2.1.3.3.1 Constellation Rotation Detection

When an additional rotation is introduced for the α-QPSK modulation, the MS needs to detect it blindly, as mentioned in section 8.1.4. While MUROS receiver performance in sensitivity limited scenario is presented in section 8.2.1.2.2.2, Figure 8-45 depicts the performance degradation of the same receiver when the α-QPSK carrier is exposed to GMSK modulated MTS-2 interference.

The performance is shown for codecs TCH/HS, TCH/AHS5.9 and TCH/AFS12.2 when the alpha-QPSK modulation constellation is determined by alpha 0.634, 1 and 1.264. The degradation at 1% FER is at most 0.15 dB at SCPIR=+6 dB compared to performance when no modulation needs to be detected. At SCPIR=0 dB and SCPIR=-6 dB no degradation is seen.

As the degradation due rotation detection never exceeds 0.15dB for any of the studied alpha values it will be compensated by the PAR enhancement presented in Figure 8-7.

Table 8-11: Alpha versus relative sub-channel power

α	SCPIR [dB]
0.634	-6
1.0	0
1.264	6

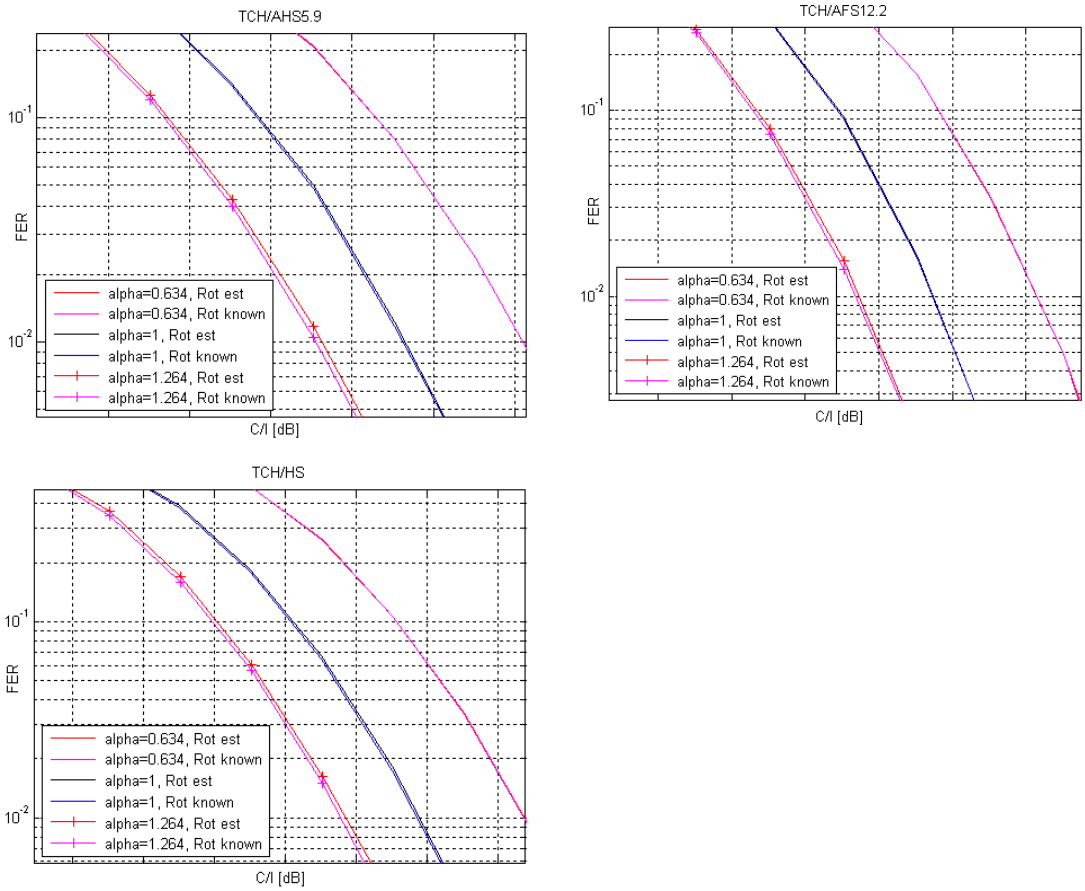

Figure 8-45: MUROS receiver with/without rotation detection when speech codec TCH/HS, TCH/AHS5.9 and TCH/HS12.2 is used. Each tick on the x-axes corresponds to 2dB

It should be noted that the MUROS receiver estimates the rotation on a burst-by-burst basis. If the blind rotation detection metric were to be accumulated over several bursts, the performance is expected to be improved.

8.2.1.3.3 SIC receiver

From the simulations shown below it can be concluded:

- There is little difference in performance (for both reference and SIC) between the cases with MS speed of 3 km/h and 50 km/h.
- The performance in the MTS-2 (synchronous, multiple interferers) and MTS-4 (asynchronous, multiple interferers) test cases is also very similar, for both reference and SIC receivers.
- In most test cases the performance of the weakest sub-channel is inferior to the performance of the reference MRC receiver at 1% FER. The degradation is between 2 and 6 dB (when comparing C1/I) for a sub-channel power imbalance ratio less than or equal to 10 dB. Since a legacy IRC receiver exhibits much better performance than an MRC receiver in interference scenarios, the degradation with respect to a legacy IRC receiver can be very large, roughly from 6 to 20 dB, depending on the IRC algorithms and the test case.

8.2.1.4 Results from: MUROS - Performance of Alpha-QPSK with Legacy DARP MS

Text in this section originates by Nokia Corporation in [8-14].

The text in this section has been contributed by Nokia in [8-14]. This section presents the sensitivity and interference performance of legacy DARP MS receiving an alpha-QPSK [8-16] MUROS sub channel. For interference performance verification the four MUROS Test Scenarios (MTS1-4) described in chapter 5 in this TR are used.

8.2.1.4.1 Simulation Assumptions

8.2.1.4.1.1 Legacy Terminals

The legacy DARP receiver applied in this section is a DARP phase I capable terminal. Such DARP terminals are widely present in the market.

8.2.1.4.1.2 Transmitted MUROS Signal

In this section, the desired DL MUROS signal is generated by alpha-QPSK symbol mapping with $\pi/2$ rotation and linearized GMSK TX pulse shape as illustrated in Figure 8-61. The receiver is a legacy DARP receiver, i.e. the received signal is being treated as a GMSK modulated signal.

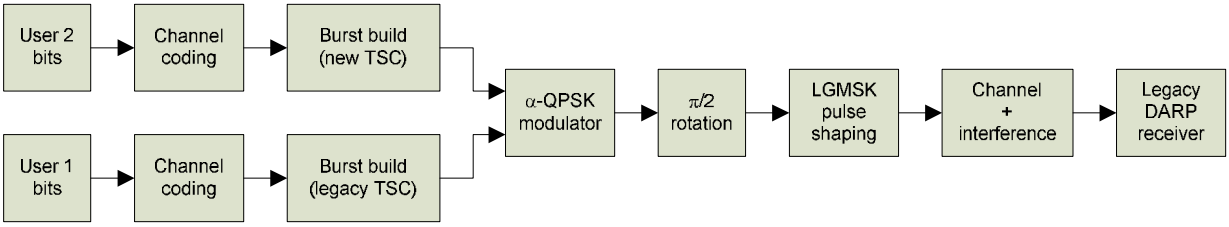

Figure 8-61: Block diagram of MUROS α-QPSK TX by mapping two users on BB and transmitted as a QPSK modulated signal

As described above in this TR, legacy training sequence codes (TSC) are applied to the first MUROS sub channel to make it fully compatible with legacy MS. For the MUROS second sub channel, the orthogonal TSCs proposed in [8-15] are assumed. The pair TSC 0 is chosen from the combined TSC set for the simulations. DTX is not applied.

8.2.1.4.1.3 Alpha-QPSK

The α-value can take any value between 0 and $\sqrt{2}$ and reflects the power ratio between the two users, where the outer values corresponds to BPSK for either user 1 or user 2 (i. e. only one user transmitted), and α = 1 correspond to equal power between the two. The constellation points for different α-values are shown in Figure 8-62. The red circle (O) correspond to α = 1.0 (which equals OSC presented in [8-15]), and the blue cross (X) corresponds to α = 0.2. Only performance of user 1 is evaluated and from user 1 point-of-view α > 1.0 will only improve performance over OSC, therefore only α ≤ 1.0 is simulated to see the performance loss of different α-values.

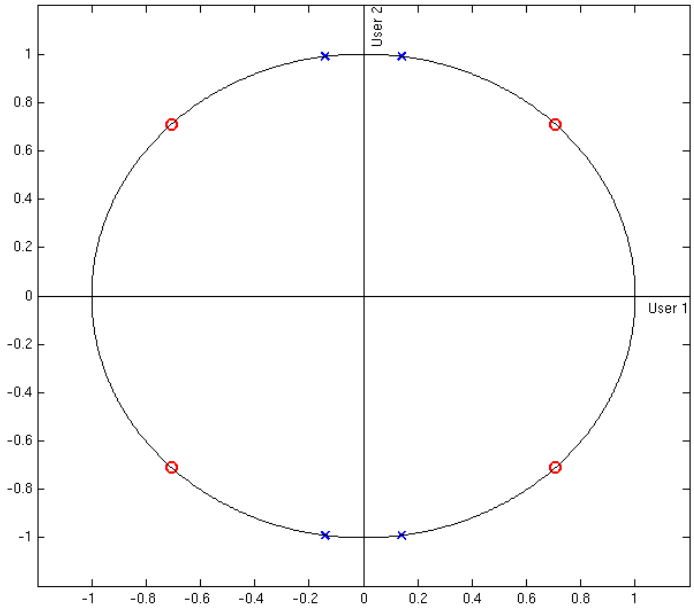

Figure 8-62: Constellation points for various values of , (O) α = 1.0 (QPSK), (X) α = 0.2

8.2.1.4.1.4 MUROS Interference Models

Sensitivity and the four MUROS Test Scenarios (MTS1-4) specified in this TR have been used for verifying the interference performance of a legacy DARP MS receiving a MUROS sub channel.

For MTS modulation QPSK modulated interference were used.

8.2.1.4.1.5 Other Simulation Parameters

The performance is presented for TCH/AFS 12.2, TCH/AFS 5.9 and AHS 5.9. A typical urban channel profile, terminal speed 3 km/h (TU3) and frequency hopping (FH) in the 900 MHz band have been used for the DL MUROS simulations. Typical MS impairments are included in the simulations.

8.2.1.4.2 Downlink Performance Results

The results in this section cover frame erasure rate (FER) as a function of C/I1 where C denotes the total power of the received MUROS signal (i.e. carrying 2 sub channels) and I1 denotes the power of the strongest co-channel interferer.

The presented performance is for the first MUROS sub channel containing the legacy TSC0. The performance of the second MUROS sub channel is not considered in this section, since changes are required to the MS receiver in order to cope with the MUROS TSC-pairs. The TSC0-pair proposed in [8-15] is used for the second MUROS sub channel. However, when the two alpha-QPSK MUROS sub channels have equal power (correspond to α = 1.0) the performance of the second channel can be assumed to be on par with the first sub channel as noted in [8-17].

First the sensitivity performance is presented in subsection 8.2.1.4.2.1, and then the interference performance for the two synchronous scenarios MTS1+2 are presented in subsection 8.2.1.4.2.2 and 8.2.1.4.2.3 respectively. The performance for the two asynchronous scenarios MTS3+4 are presented in subsection 8.2.1.4.2.4 and 8.2.1.4.2.5 respectively.

8.2.1.4.2.1 Sensitivity Performance

The sensitivity performances of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel is presented in Figure 8-63 for a MUROS sub channel using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The performance is presented for α = [0.2, 0.3, … , 1.0]

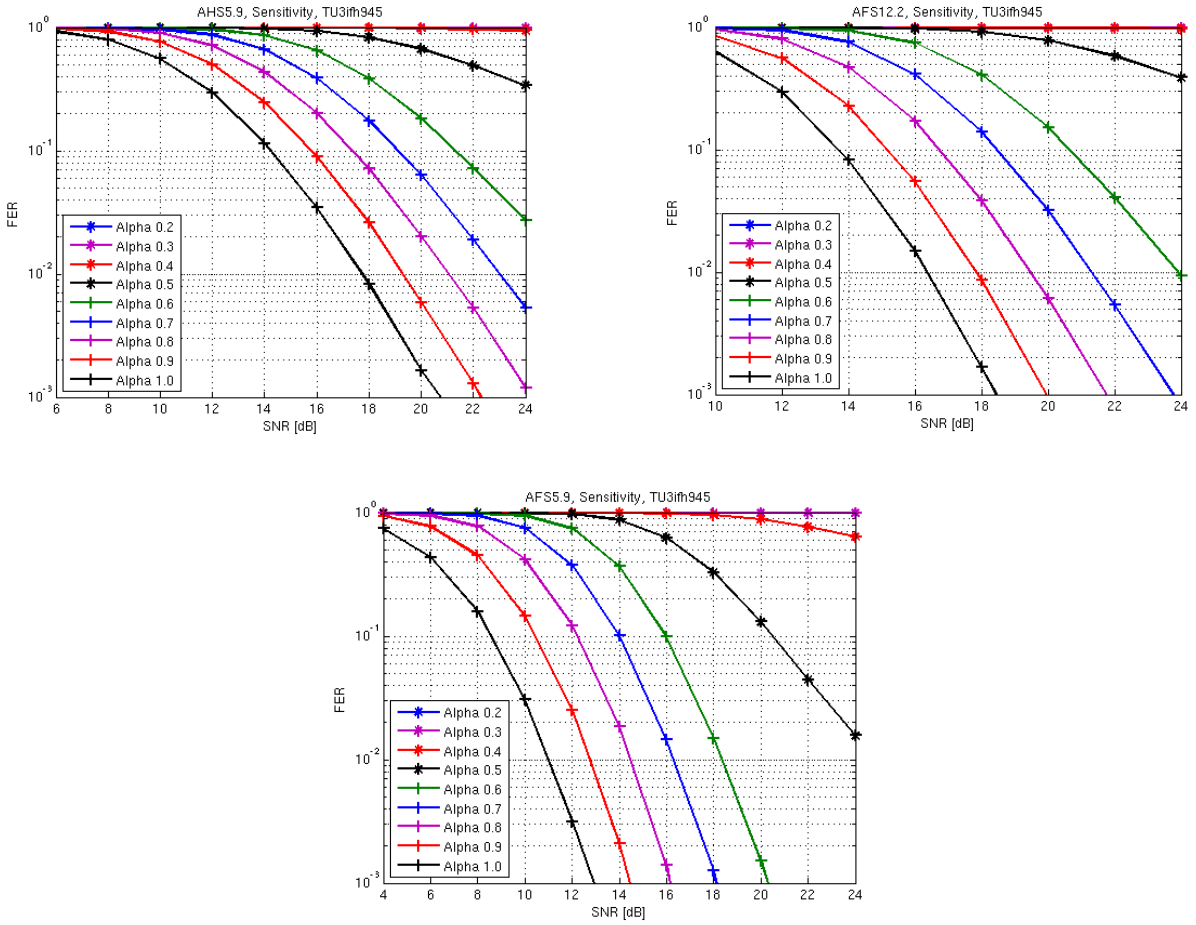

Figure 8-63: DL sensitivity performance of a legacy DARP MS receiving a alpha-QPSK MUROS sub channel for α = [0.2, 0.3, … , 1.0] using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

8.2.1.4.2.2 MTS-1 Performance

The performance of a legacy DARP MS receiving a alpha-QPSK MUROS sub channel when a single synchronous co-channel interferer is present is shown in Figure 8-64 for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The performance is presented for α = [0.2, 0.3, … , 1.0].

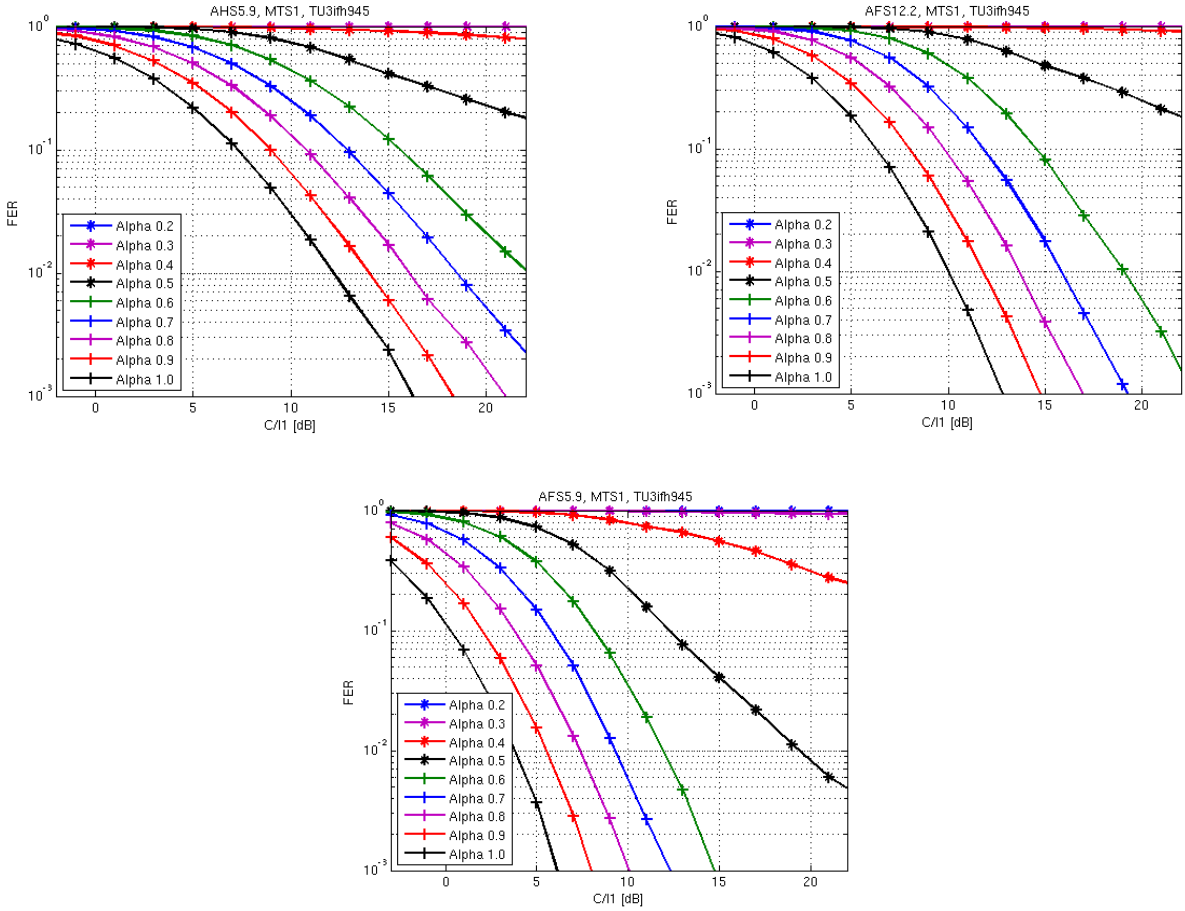

Figure 8-64: DL Co-channel interference performance (MTS1) of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel for α = [0.2, 0.3, … , 1.0] using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

8.2.1.4.2.3 MTS-2 Performance

The performance of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel when mixed synchronous interference is present is shown in Figure 8-65 for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The performance is presented for α = [0.2, 0.3, … , 1.0].

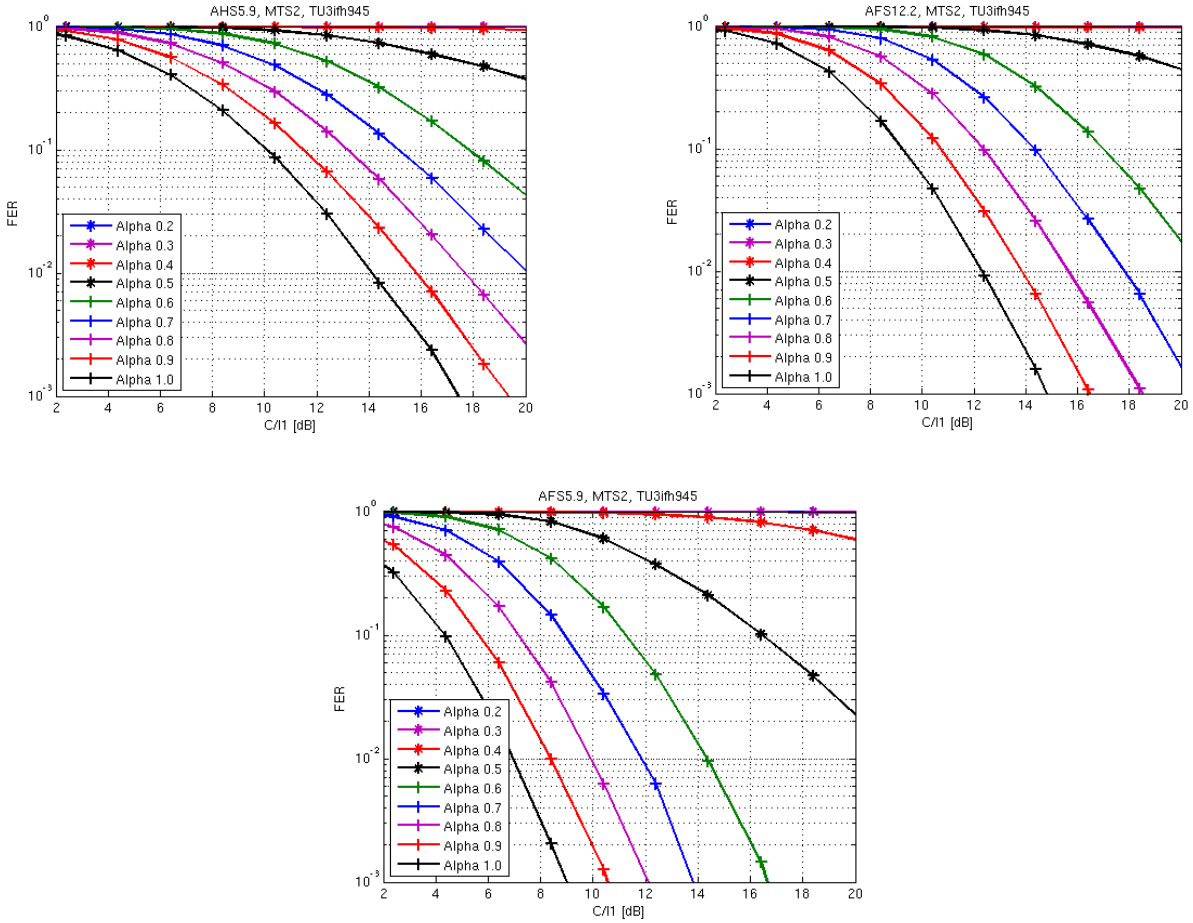

Figure 8-65: DL Mixed interference performance (MTS2) of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel for α = [0.2, 0.3, … , 1.0] using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

8.2.1.4.2.4 MTS-3 Performance

The performance of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel when a single asynchronous co-channel interference is present is shown in Figure 8-66 for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The performance is presented for α = [0.2, 0.3, … , 1.0].

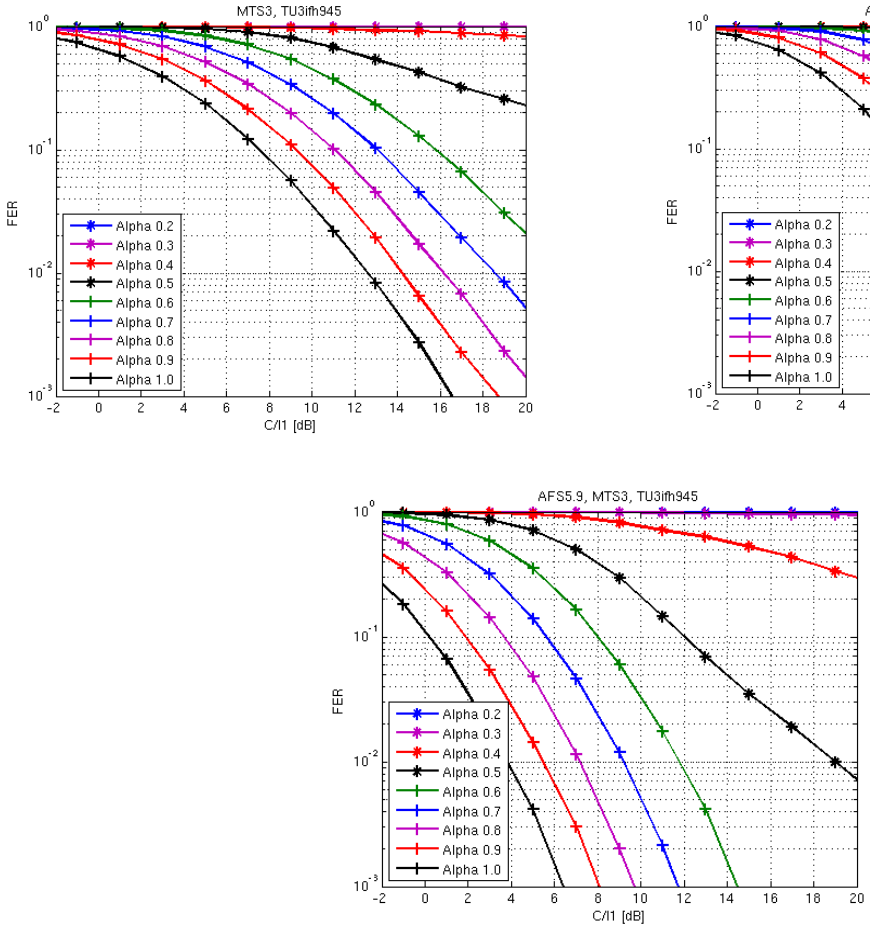

Figure 8-66: DL Asynchronous Co-channel interference performance (MTS3) of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel for α = [0.2, 0.3, … , 1.0] using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

8.2.1.4.2.5 MTS-4 Performance

The performance of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel when mixed synchronous and asynchronous interference are present is shown in Figure 8-67 for AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9. The performance is presented for α = [0.2, 0.3, … , 1.0].

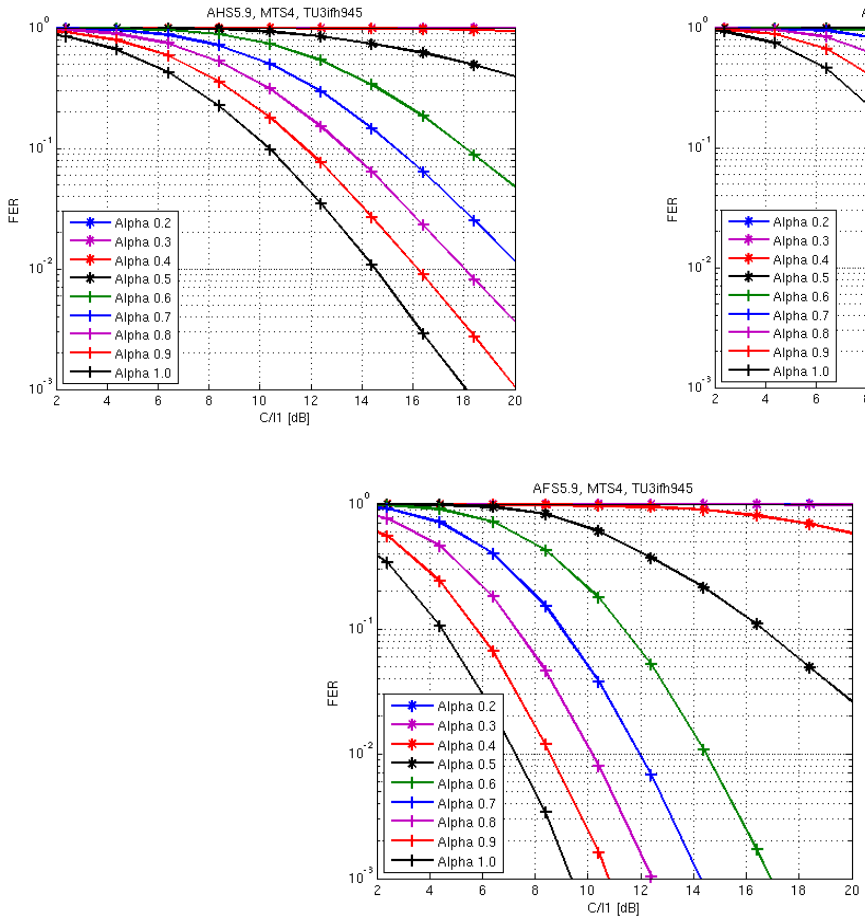

Figure 8-67: DL synchronous and asynchronous mixed interference performance (MTS4) of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel for α = [0.2, 0.3, … , 1.0] using AMR half rate 5.9, AMR full rate 12.2 and AMR full rate 5.9

8.2.1.4.3 Summary of Results

This section has presented the sensitivity and interference performance of a legacy DARP MS receiving an alpha-QPSK MUROS sub channel. For the interference performances the MTS1-4 interference scenarios were used with the interferer modulation type being QPSK.

8.2.2 Network Level Performance

8.2.2.1 Adaptive constellation rotation

System simulations have been performed to estimate the possible network gains by the introduction of adaptive symbol constellation rotation.

The investigated scenario is for 100 % MUROS MS penetration.

It should be noted that the adaptive constellation rotation will also give coverage gains in sensitivity limited scenarios, but this has not been evaluated in this investigation.

The investigated scenario is MUROS-2 where a backoff of 3.3 dB and 2.6 dB has been investigated.

The impact on different QPSK backoff is investigated and Figure 8-68 shows the spectral efficiency at the non-MUROS reference case, at 3.3 dB QPSK power backoff and at 2.6 dB QPSK power backoff.

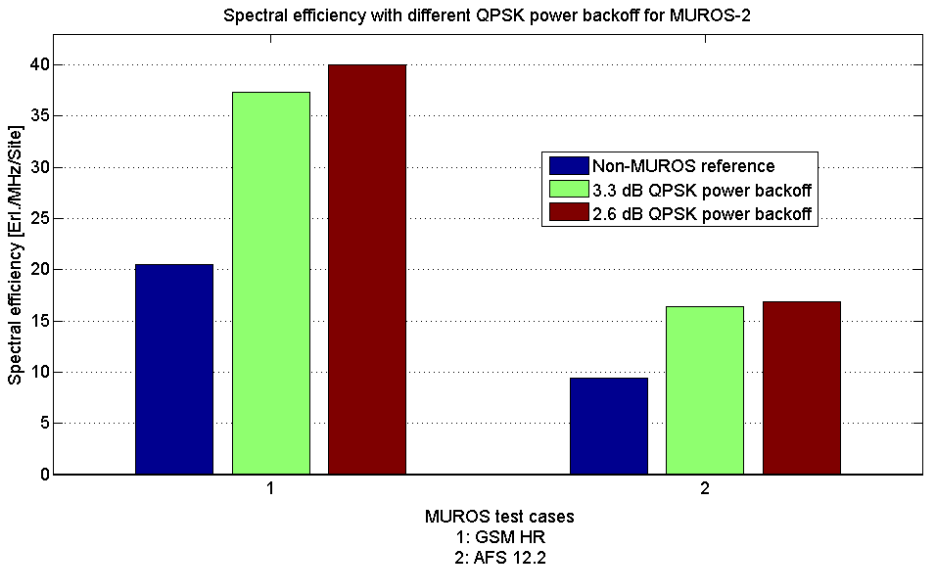

Figure 8-68: Spectral efficiency MUROS-2

The gains for test case A and B are presented in Table 8-12. No values are presented for test case C (AFS 5.9) since this case is block limited and will not give any gain. Case D is still left TBD.

Table 8-12: Capacity gain using different QPSK

Type	Gain at QPSK power backoff: 3.3 dB	Gain at QPSK power backoff: 2.6 dB
A	82% (*)	95% (*)
B	75%	80%
C	Block limited	-

* Gain presented at 96% satisfied users

It can be seen that there are gains of approximately 5 - 13 %-units in spectral efficiency by using 2.6 dB backoff compared to the case of using a 3.3 dB backoff.

NOTE 1: The degradation due to the blind modulation detection evaluated in section 8.2.1.3.3.1 has been shown to be 0 dB at α=1.

NOTE 2: No sub channel power control has been used in the system simulations.

8.3 Impacts on the Mobile Station

8.3.1 Legacy mobile stations

The presented concept is compatible with legacy MS. No implementation impact is foreseen. In addition, it should be noticed that legacy mobiles will gain from both the sub channel specific power control on the DL and the proposed frequency hopping scheme.

8.3.2 Mobile stations supporting Adaptive symbol constellation

Support of new TSCs will help improve link performance, spectral efficiency and network planning. Thus, new training sequence codes must be defined in the MS. The support of the new training sequence codes must be signalled to the network.

In order to improve the link performance and ultimately the spectral efficiency of the network, the MS receiver algorithms should be optimized to cope with inter-sub-channel interference.

Sub channel power control on the DL (α-QPSK)

No additional implementation is needed to support sub channel power control on the DL for an MS detecting its own sub channel, e.g. a SAIC capable MS.

If a joint detection algorithm is used, i.e. the two sub channels are detected jointly, the power control parameter α needs to be estimated on a burst-by-burst basis or by a filtering over several bursts. Alternatively, signalling could be used to convey α. NOTE: Estimation of alpha is only needed for joint detection receivers.

Adaptive constellation rotation

In order to support adaptive constellation rotation the MS must perform blind detection of the rotation angle.

Frequency hopping

There is no impact to the legacy mobile allocated on the first sub channel. The user on the second sub channel needs to support additional signalling and the new hopping sequences.

8.4 Impacts on the BSS

The transmitter will need to implement a new linear modulation type. A receiver capable of demodulating multiuser MIMO signals is also required. New power control and channel allocation strategies must also be implemented. The following list provides more details:

BSS shall be able to assign different TSC"s to the two users. The choice of TSC shall be made based upon the capabilities of the MS.

The transmitter shall implement the linear modulator. If a legacy BSS has support for a linear M -PSK modulator, $M \geq 4$, then α can be quantized to a set of discrete values and the legacy modulator re-used.

The transmitter should be able to support two rotations, which are used dependent on the value of alpha.

The receiver shall be able to demodulate 2 simultaneous received signals from two antenna branches. (I.e. a 2 user MIMO receiver is needed.).

The transmitter and receiver should support new signalling for frequency hopping and new frequency hopping schemes.

The BSS shall implement new power control algorithms both in the uplink and downlink. In the downlink it is necessary to ensure that each MS has a signal to noise plus interference ratio high enough to successfully demodulate and decode its intended signal. This is achieved by choosing the parameter α and the output power appropriately.

Adaptive symbol constellation will only impact the radio interface in terms of increased channel capacity. Thus, the capacity of the Abis interface will have to be increased in accordance with the increased number of channels that can be supported by Adaptive Symbol Constellation.

8.5 Impacts on Network Planning

No impact on network planning is foreseen. The impact on system performance due to a wider pulse shape is left FFS.

8.6 Impacts on the Specification

Below is a list of impacted specifications for the Adaptive Symbol Constellation concept:

3GPP TS	Details
24.008	Capability indication for adaptive symbol constellation
44.018	Layer3, training sequence signalling

45.002	Definition of new training sequence codes Frequency hopping impacts
45.004	α-QPSK modulation definition
45.005	Performance requirements for UL and DL
45.008	Impacts on power control
51.010	Introduction of new mobile station test cases
51.021	Introduction of new base station test cases

8.7 Summary of Evaluation versus Objectives

In this section the candidate technique is evaluated against the defined objectives in chapter 4. Note, this section represents the view of the proponents of this candidate technique.

The following classification is used for the evaluation:

Fulfilled

Expected to be fulfilled

Unclear/FFS

Not fulfilled

8.7.1 Performance objectives

Capacity improvements at the BTS (P1)

Gains have been shown in [8-11] to be between 0 and 114 % dependent on the system scenario and speech coded investigated. Further enhancements are expected when utilizing α-QPSK, frequency hopping and adaptive constellation rotation.

Expected to be fulfilled

Capacity improvements at the Air interface (P2)

Two users are multiplexed on the same radio resource.

Fulfilled

Evaluation of MUROS Candidate Techniques	**Candidate Techniques proposed in MUROS**
Performance Objectives	**Adaptive symbol constellation**
P1: Capacity Improvements at the BTS 1) increase voice capacity of GERAN in order of a factor of two per BTS transceiver 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Gains have been shown to be between 0 and 114 % dependent on the system scenario and speech coded investigated for OSC. Further enhancements are expected when utilizing α-QPSK, frequency hopping and adaptive constellation rotation.
	2) All codecs are supported
P2: Capacity Improvements at the air interface 1) enhance the voice capacity of GERAN by means of multiplexing at least two users	1) Two users are multiplexed on the same radio resources

simultaneously on the same radio resource both in downlink and in uplink 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	2) All codecs are supported

8.7.2 Compatibility objectives

Maintenance of Voice Quality (C1)

The capacity gains have been shown when using the same quality target for channels not using adaptive symbol constellation and channels using adaptive symbol constellation. Additionally, GSM HR has been investigated with the same FER threshold as AMR codecs. Given the same FER level, the voice quality is worse for GSM HR than for any AMR codec.

Fulfilled

Support of legacy mobile stations (C2)

Legacy, DARP Phase I, mobiles can be supported on the first sub channel, see [8-10], while MS"s supporting new training sequence codes are required for the second sub channel.

Both the concept of downlink power control (α-QPSK) and the concept of frequency hopping will support legacy mobiles. However, legacy mobiles will experience no gains from adaptive constellation rotation.

The support of non DARP Phase I mobiles is still left FFS.

Fulfilled (DARP Phase I MSs)

TBD (Non DARP Phase I MSs)

Implementation Impact to new Mobile Stations (C3)

Compared to a legacy DARP Phase I receiver, the following additional support is needed.

- new training sequences
- additional detection of rotation. (Note: Algorithms for modulation detection in EDGE capable terminals can be re-used.)
- signaling procedure of frequency hopping
- frequency hopping support,

Implementation Impacts to BSS (C4)

Transmitter:

- additional constellation rotation
- linear modulator for α-QPSK

Receiver

- Dual antenna receiver becomes mandatory.
- Demodulation algorithm of two simultaneous received signals

Transmitted and Receiver

- new TSC support
- support of frequency hopping concept

Dimensioning aspects of the Abis interface due to the increased channel support needs to be taken into account.

Impacts to Network Planning (C5)

No impact is foreseen when using the linearized GMSK pulse shape. The impact due to a wider pulse shape on the DL is left FFS.

The evaluation against the objectives is summarised in the table below.

The compatibility objectives are summarized below with following colour coding.

Fulfilled

Expected to be fulfilled

Unclear/FFS

Not fulfilled

Evaluation of MUROS Candidate Techniques	**Candidate Techniques proposed in MUROS**
Compatibility Objectives	**Adaptive symbol constellation**
C1: Maintainance of Voice Quality 1) voice quality should not decrease as perceived by the user. 2) A voice quality level better than for GSM HR should be ensured.	1) Only users experiencing good enough quality will be allocated on a channel supporting alpha-QPSK. Simulations have shown that there are no losses in user satisfaction, only gains, when using the new technique.
	2) GSM HR has been investigated with the same FER threshold as AMR codecs. Given the same FER level, the voice quality is worse for GSM HR than for any AMR codec.
C2: Support of Legacy Mobile Stations 1) Support of legacy MS w/o implementation impact. 2) First priority on support of legacy DARP phase 1 terminals, second priority on support of legacy GMSK terminals not supporting DARP phase 1.	1) Legacy, DARP Phase I, mobiles can be supported on the first sub channel. Both the concept of downlink power control (α-QPSK) and the concept of frequency hopping will support legacy mobiles.
	2) Legacy DARP Phase I terminals will be supported. Non DARP Phase I terminals have been shown to support the concept on link level. System level studies are still needed to show the feasibility of non DARP Phase I support.
C3: Implementation Impacts to new MS's 1) change MS hardware as little as possible. 2) Additional complexity in terms of processing power and memory should be kept to a minimum.	1) New training sequences, additional rotation (note that blind modulation detection algorithms from EGPRS can be re-used) and new frequency hopping functionality need to be supported. If joint detection receiver is used, the alpha (in the alpha-QPSK constellation), needs to be estimated.
	2) Detection of one additional rotation is a low complexity/low memory operation and can be done in the same way as in modulation detection in EGPRS. If joint detection receiver is to be used then the demodulator will be considerably more complex than the GMSK demodulator. In this case the estimation of

	alpha is also required. Estimation of alpha is slightly more complex than the detection of one additional rotation.
C4: Implementation Impacts to BSS 1) Change BSS hardware as little as possible and HW upgrades to the BSS should be avoided. 2) Any TRX hardware capable for MUROS shall support legacy non-SAIC mobiles and SAIC mobiles. 3) Impacts to dimensioning of resources on Abis interface shall be minimised.	1) Demodulation of two simultaneous signals is needed. Additionally support of new training sequences, linear modulator for alpha-QPSK, additional rotation and support of new frequency hopping scheme needs to be supported.
	2) The concept brings no impact to the support of different type of mobiles for the TRX
	3) The capacity of the Abis interface needs to be increased in accordance with the increased number of channels supported by MUROS.
C5: Impacts to Network Planning 1) Impacts to network planning and frequency reuse shall be minimised. 2) Impacts to legacy MS interfered on downlink by the MUROS candidate technique should be avoided in case of usage of a wider transmit pulse shape on downlink. 3) Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator"s band allocation and in country border regions where no frequency coordination are in place.	1) No impact on frequency planning or frequency re-use is foreseen.
	2) A wide pulse shape has only been investigated on link level. System level simulations are needed to investigate the impact of a wider pulse.
	3) If a wide pulse shape is to be deployed it is not expected to be used at the edge of an operator"s frequency band.

9 Higher Order Modulations for MUROS

9.1 Concept Description

9.1.1 Downlink

9.1.1.1 Speech multiplexing

For the downlink channel, several speech channels can be transmitted simultaneously over a single physical channel. Each channel can be separately encoded. This technique support all legacy speech codecs (TCH/FS, TCH/EFS, TCH/AFS, TCH/WFS, TCH/HS, TCH/AHS), and separate DTX for each user. In the case that AMR speech encoding is being used for one or more of the users, this allows for independent selection of codec mode for each user, multiplexing of legacy users. A diagram showing the concept of multiplexing four users is shown in Figure 9-1.

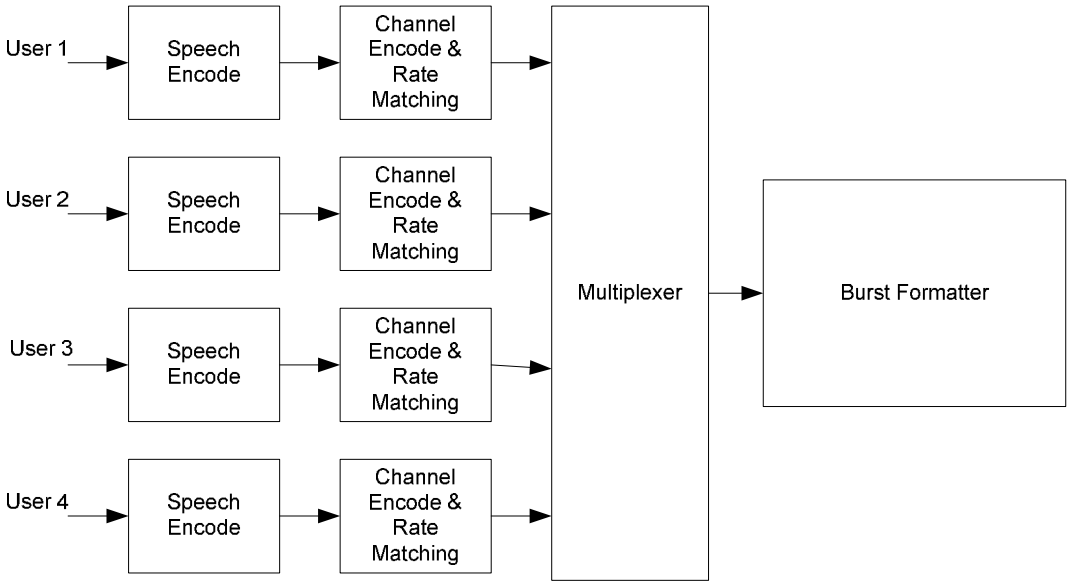

Figure 9-1: Higher Order Modulation for MUROS in Downlink (4 users)

As can be seen in Figure 9-1, each user is separately encoded. After rate matching, the users are multiplexed together. There are several policies the multiplexer could take. One option is to fairly divide the resource among the users. For example, by concatenating the users" messages and then bit interleaving, or by allocating separate symbols for every user. In order to allow power control between the users the number of bits the rate matching outputs can be unequal. Another option that can be used is allocating each user a bit (or bits) in the modulation constellation. This option allows inherent power control, as the strength of bits is not equal. This is discussed in more detail in the section on power control.

Using this method, one can multiplex 1 to 4 users on the same slot. As in TCH/AFS, each speech frame is interleaved over 8 physical slots to allow as large as possible time diversity. The four MUROS users are marked as M0,…,M3. In each slot, up to 4 users are transmitted, depending on each user"s individual DTX status. The modulation level can be varied according to the instantaneous number of users as shown in Figure 9-2.

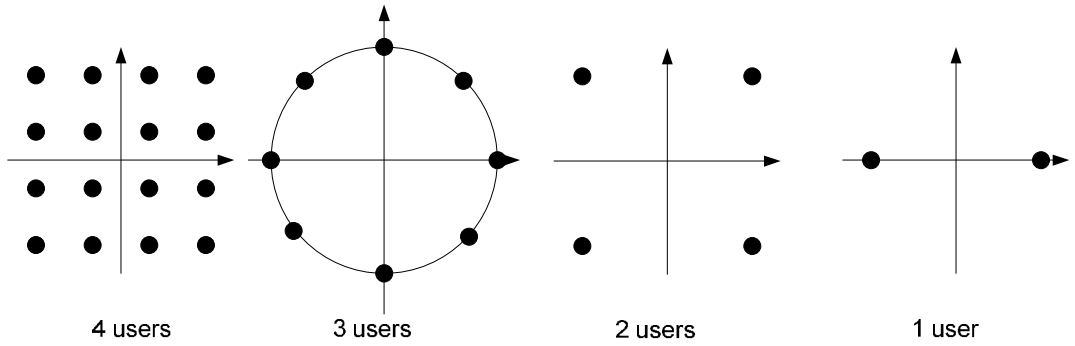

Figure 9-2: Modulation according to Number of Configured Users

9.1.1.1.1 Speech Multiplexing and Interleaving

The allocation of the symbols on the constellation is done according to the order of bit definition in 45.004. In GMSK, S0 is the only bit in the constellation, di. In QPSK, S0 is mapped to the first bit and S1 to the second bit d2i and d2i+1 respectively. In 8PSK, S0, S1 and S2 are mapped to bits d3i,, d3i+1 and d3i+2 respectively, and in 16QAM stream S0 to S3 are mapped to bits d4i, d4i+1, d4i+2 and d4i+3 respectively. Using this definition, in 8PSK modulation streams S0 and S1 are 'strong' streams, as they are mapped to strong bits, while S2 is a 'weak' stream, as it mapped to a weak bit. In 16QAM, stream S0 and S1 are the strong streams and stream S2 and S3 are the weak streams.

In case of 4 users, the stream allocation to user allocation is done in the following way: M0 to S0, M1 to S1, M2 to S2 and M3 to S3. In case of only one active user, that user will be mapped to the GMSK S0 stream. In other cases, the mapping will depend on the instantaneous DTX status, as will be described in the DTX subsection.

Each user that is transmitted has an allocated user stream in the constellations. As the number of bits in each stream is equal to the legacy number of bits in the TCH channel, speech multiplexing can be done as currently done in TCH/AFS channels, with the interleaving onto the allocated bits. As with legacy channels, adjacent speech frames are diagonally interleaved in the same way.

The interleaving pattern used by each user is depending on the user number. The interleaving is done in the following way:

Let C(k), k=0,…,455, be the coded bits after puncturing, and I(j),j=0,…,455 be the coded bits after interleaving.

Define j as: j = 57*(k%8) + (49*k+14*index)%57, where ind the MUROS user index, given in Table 9-0. The interleaving pattern is defined as I(j) = C(k).

Using this interleaving, user M0 has the the same legacy interleaving, therefore if only M0 is transmitted, the legacy TCH/AFS slots are achieved.

Table 9-0: MUROS user interleaving indices

User	Index
M0	0
M1	1
M2	2
M3	3

9.1.1.2 Modulation Schemes and Training Sequences

The proposal will re-use GMSK and 8-PSK modulation training sequences, and 16-QAM modulation training sequences defined for EGPRS2. In addition, 8 training sequences for QPSK modulation at normal symbol rate will need to be defined. This can using the same method of producing the 16QAM/32QAM sequences. A rotation of $3\pi/4$ can be used to differentiate the modulation scheme for blind modulation detection. The TSCs are summarized in Table 9-0a.

Table 9-0a: QPSK Training Sequences

Training Sequence Code (TSC)	Training sequence
0	1,1,1,1,0,0,1,1,1,1,0,0,1,1,0,0,0,0,0,0,1,1,1,1,1,1,1,1,0,0, 1,1,1,1,1,1,1,0,0,1,1,1,1,1,0,0,1,1,0,0,0,0,0,0
1	1,1,1,1,0,0,1,1,0,0,0,0,1,1,0,0,0,0,0,0,1,1,0,0,0,0,0,0,0,0, 1,1,1,1,1,1,1,0,0,1,1,0,0,0,0,1,1,0,0,0,0,0,0,0
2	1,1,0,0,1,1,1,1,1,1,1,1,1,0,0,0,0,0,0,1,1,0,0,0,0,0,1,1,0,0, 1,1,1,1,1,0,0,1,1,1,1,1,1,1,1,1,0,0,0,0,0,0,1,1

7	0,0,0,0,0,0,1,1,0,0,0,0,0,0,0,0,1,1,1,1,1,1,1,0,0,1,1,1,1,1,0,0, 1,1,0,0,0,0,0,0,1,1,0,0,0,0,0,0,0,0,1,1,1,1

Constellation rotations can be as for EGPRS2, with the exception of the QPSK configuration to support a legacy GMSK user. This is described in clause 9.1.1.3.

9.1.1.3 Legacy GMSK MS Support

Support for legacy GMSK MSs can be provided with a modified QPSK modulation. In this case, the resource can support up to 2 MSs, one of which can be a legacy GMSK MS. The constellation rotation will be compatible with legacy GMSK for transmission of this slot, i.e. π/2 per symbol period, as shown in Figure 9-3. Detection of the rotation will be by blind modulation detection, as for detection between different modulation schemes for the regular speech multiplexing. Figure 9-4 shows different configurations for multiplexing legacy MSs, both full rate and half rate.

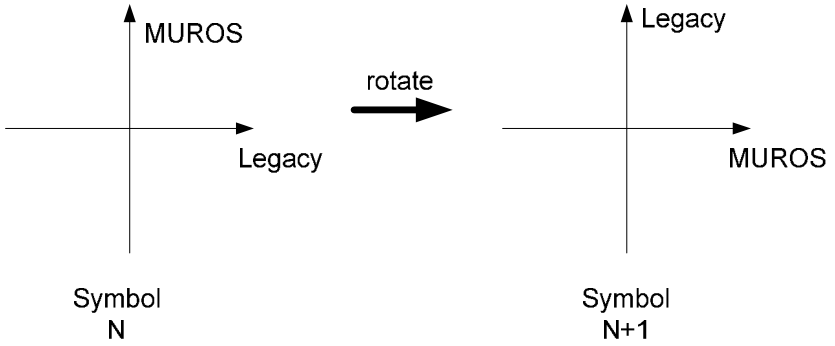

Figure 9-3: π/2 constellation rotation for legacy multiplexing

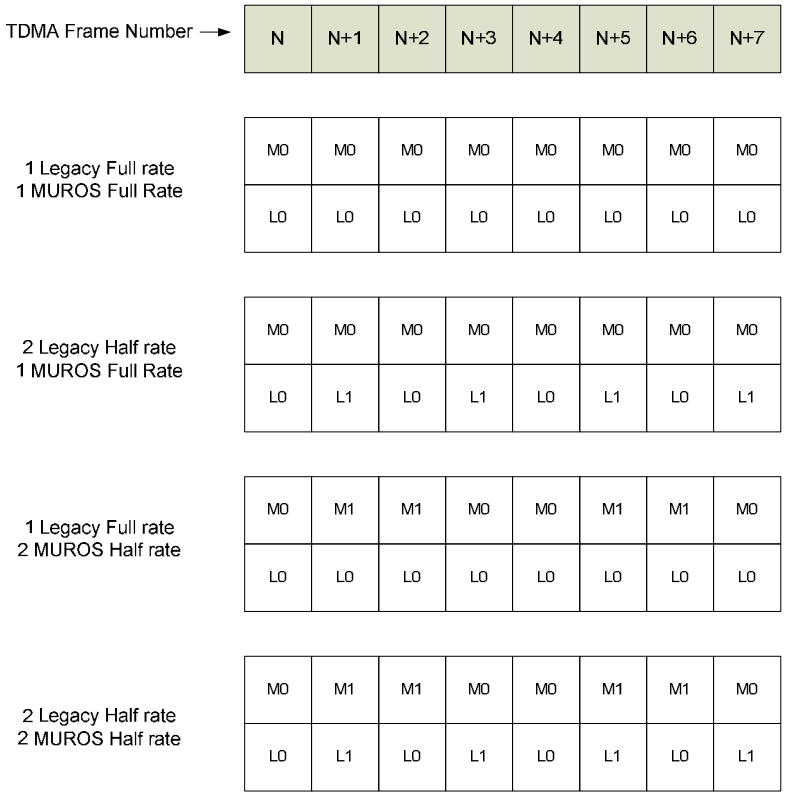

Figure 9-4: Downlink Configurations of MUROS with Legacy

9.1.1.4 Codecs support and Achievable Code Rates

This HOM technique support all legacy speech codecs (TCH/FS, TCH/EFS, TCH/AFS, TCH/WFS, TCH/HS, TCH/AHS), and separate DTX for each user. In full rate codec is supported in the following way. Every legacy codec produce a payload of 456 bits. This payload is interleaved using the interleaving scheme described in subsection 9.1.1.2. After interleaving, the payload bits are mapped to the user stream over 8 slots as done the legacy full rate channels.

The achievable coding rate are equal to the legacy coding rate, as the same payload size is maintained, i.e. 456 bits.

The support of the legacy codes is done in the following way. Every half rate code produces 228 bits. Those bits are duplicated to produce a total of 456 bits. Ones 456 bits are achieved, we continue as in the full rate codecs, i.e., interleaving and mapping on the appropriate stream.

As explained in the above text, the achievable code rate is the same as achieve in the legacy codec for every modulation. As a reference, Table 9-1 summarized the TCH/AFS code rates for any modulation used.

Table 9-1: AMR channel coding rates on DL

AMR	AMR code rate (no header)
TCH/AFS12.2	0.56
TCH/AFS10.2	0.47
TCH/AFS7.95	0.37
TCH/AFS7.4	0.34
TCH/AFS6.7	0.31
TCH/AFS5.9	0.28
TCH/AFS5.15	0.24
TCH/AFS4.75	0.23

9.1.1.5 DTX

The decision for each DL user channel to activate DTX is independent, depending on instantaneous speech activity. In the case that one or more users enter DTX, a lower, more robust modulation can be used according to the number of users instantaneously required. For example, where four users use 16-QAM, 3 users can use 8PSK, two users QPSK, and one user GMSK modulation.

Since information about which user or users enter DTX is not known a priori, this information must be provided by signaling as side information. This can be done as for the following example.

Each user of a logical channel is a priori assigned an identifier, so that the user knows where to access the channel encoded bits. So, the user will always know which vector of decoded bits to extract from a received burst. The different DTX configurations are now considered.

9.1.1.5.1 DTX Configuration Signaling

Signaling of the MUROS users that are active for a given slot transmission can be done with a single bit.

Suppose that there 4 MUROS users, numbered for a given TDMA frame as M0, M1, M2, and M3. Each MS is aware apriori of its index for this phase in the hop sequence. This information is signaled at call setup. The interleaving order is preserved also in the case that one or more of the channels enters DTX.

The signaling may then work as follows.

4 users - 16-QAM

All four users are transmitted. No signaling is required. User M0 is carried on stream S0, M1 on S1, M2 on S2 and M3 on S3.

3 users - 8-PSK

One user has entered DTX. Four options are possible for transmitted channels. A signal bit is used to indicate the appropriate channel configuration as shown in Table 9-2.

Table 9-2: Signalled Bit Encoding according to DTX states

S0 S1 S2	
M0 M1 M2	0
M0 M1 M3	0
M0 M2 M3	1
M1 M2 M3	1

In the 8-PSK slot transmission there are 3 streams S0, S1 and S2, of encoded channel bits, each equivalent in size to the payload carried by a GMSK slot. The four users relate to the signaled bit as shown in Table 9-3. So for example, when the signaled bit is set to 1, the MUROS user with index 2 (M2), reads the third vector of bits, S2.

Table 9-3: Interpretation of Signaled Bit By MUROS user

Signalled Bit	M0	M1	M2	M3
0	S0	S1	S2	S2
1	S0	S0	S1	S2

2 users - QPSK

Two users have entered DTX. Six options are possible for transmitted channels. A signal bit is used to indicate the appropriate channel configuration as shown in Table 9-4.

Table 9-4: Signalled Bit Encoding according to DTX states

Transmitted channels	Signalled Bit
S0 S1	
M0 M1	1
M0 M2	0

M0 M3	1
M1 M2	0
M1 M3	0
M2 M3	1

In the QPSK slot transmission there are 2 streams, S0 and S1, of encoded channel bits, equivalent is size to the payload carried by a GMSK slot. The four users relate to the signaled bit as shown in Table 9-5. So for example, when the signaled bit is set to 1, the MUROS user with index 2 (M2), reads the third vector of bits, S2.

Table 9-5: Interpretation of Signaled Bit By MUROS user

Signalled Bit	M0	M1	M2	M3
0	S0	S0	S1	S1
1	S0	S1	S0	S1

1 user - GMSK

In the case that only a single user is not in DTX, no signaling is required. All users on this timeslot/frequency will receive the slot, and use it to try to decode a speech frame. However, only the user to whom the data is transmitted will succeed in decoding the speech frame.

9.1.1.5.1.1 Examples

M0 user

A user allocated M0 always reads the first stream of bits, irrespective of the modulation used. Since the user order is preserved, the first stream S0 will always carry M0 data, irrespective of the DTX state of other users, except in the case that M0 itself has entered DTX. The DTX signaling bit can be ignored by user M0. In the case that M0 is one of the users that is in DTX, the received data will not be decodable, since the encryption scrambling will be different from that for M0.

Note that MEAN_BEP & CV_BEP are parameters that are dependent only on uncoded data, not on data at frame level. So frames that are not decoded are not relevant to determining downlink channel quality.

Similarly, a user allocated to M3 always takes bits from the last stream of the transmitted modulation, which is S3 for 16-QAM, S2 for 8-PSK, S1 for QPSK; and, if GMSK is used, then the single stream of bits is used by M3 as the received data for speech frame decoding. The DTX signaling bit can be ignored by user M3.

M2 user

Suppose a user is allocated identifier M2 at setup together with 3 other users, allocated as M0, M1 and M3. For 16-QAM modulation transmitted on the downlink, M2 reads data bits from stream S2.

At a point in the call, one of the users on the downlink enters DTX. From the start of the next interleaved speech frame, the modulation transmitted is now 8-PSK. At this point, as the next timeslots are received, user M2 is not yet aware which user has entered DTX (including if it is M2 itself). After receiving all the timeslots of the interleaved speech frame, the DTX signaling information for that speech frame can be decoded. If the signaling bit is 0, then bits for M2 are read from stream S2 (per Table 9-3) (corresponding to M3 being in DTX (or M2 itself)). If the signaling bit is 1, then bits for M2 are read from stream S1 (corresponding to either M0 or M1 being in DTX). As for the M0 example above, if it is M2 itself that has entered DTX, then the received data will not be decodeable, but since the data is not directed to M2, this is not relevant.

Suppose now that 2 users enter DTX, and QPSK is transmitted on the downlink. If the DTX signaling bit is 0, then M2 reads its bits from the second stream S1 (per Table 9-5) (corresponding to either M0 or M1, plus M3 (or M2)), being in DTX. If the DTX signaling bit is 1, then bits for M2 are read from the first stream S0 (corresponding to both M0 and M1 being in DTX).

In the case that 3 users enter DTX, and GMSK is transmitted on the downlink, then bits for M2 are read from the single stream S0.

9.1.1.5.2 Signalling Rate and Signaling Channel Coding

In order to signal the instantaneous user channel configuration for 8-PSK and QPSK slot transmissions, one signaling bit is required. As the DTX status can be changed every speech block, the required rate of the signaling is one signaling bit per 4 slots. In order to make this transmission robust, it must be encoded. A code rate of 1/8 is used. The code words are specified in Table 9-5a.

Table 9-5a: Signaling Bit Codewords

Signaling bit	Codeword
0	0 0 0 0 0 0 0 0
1	1 1 1 1 1 1 1 1

In order to convey the signaling codeword, 8 bits per 4 slots are needed to be transmitted, that is 2 bits per slot. In QPSK modulation, this will affect only one bit per user per slot, a total of 4 payload bits in one speech frame. For example, for 12.2kbps AMR channel, this would change the channel encoding rate from R=0.56 (250/448) to R=0.563 (250/444). The impact of this on speech channel performance is expected to be negligible. Note that all simulation results include impact of the signalling.

In 8PSK the same number of bits is needed per slot. In order to improve the signaling performance, strong bits are used. Therefore user on stream S2 is unaffected in the coderate, while user in stream S0 and S1 has the same impact as in QPSK.

The signaling codeword is interleaved over 8 slots using the same way the stealing bits are interleaved. The bits that are used to convey the signaling are the strong bits. The symbol that is used to convey the signaling is symbol number 116, such that in QPSK all the symbol is used and in 8PSK only the two strong bits are used.

9.1.1.5.3 Average Channel Usage

The average active part of the DTX of an MS is typically 60%. Assuming that we multiplex 4 users simultaneously onto a physical channel, the distribution of usage among the different modulation schemes can be estimated.

Assume that for a given timeslot, the usage of a given MS, is given by a uniformly distributed variable, $p(u) = 0.6$. The usage of DTX by each MS is independent, then the number of channels instantaneously in use is distributed as:

$$P(k) = {}^4C_k (0.6)^k (0.4)^{(4-k)}$$

This gives the modulation probability distribution as shown in Table 9-6. This shows that most of the transmissions use a modulation no higher than 8PSK. Only when none of the 4 users is in DTX, then the modulation rises to 16-QAM.

Table 9-6: Modulation Usage in DTX

Modulation	Probability
16-QAM	6%
8PSK	24%
QPSK	30%
GMSK	24%
None	6%

9.1.1.6 Hopping

The DTX phase of an MS tends to be for a period of time, and does not change from speech frame to speech frame. So the improvement in channel conditions is localized to certain periods in time.

Some consideration of this has been given for the case where only 2 users are multiplexed [9-8], where adaptive frequency hopping has been proposed to hop between hopping sequences, and so better distribute the improvements available from DTX phases. Although the case for 4 multiplexed users is somewhat better in terms of improvements from DTX, since there are a number of multiplexed users that can each enter DTX, the improvements still remain somewhat localized. The concept presented in [9-8] can also be used for higher modulations. A simple example is

shown in Table 9-7 for 8 MSs, distributed over 2 hopping sequences. Initially, the MSs are distributed {M0,M1,M2,M3} and {M4,M5,M6,M7} over the 2 carriers in frame N. In frame N+1, the allocation is changed to {M0,M1,M2,M7}, {M4,M5,M6,M3}. As can be seen in Table 9-7, the second and third users are set as fixed during 4 frames. This fact is used in the signaling coding that was described in subsection 9.1.1.5. After the 4 frames, users M2 and M6 change location in order to improve the DTX diversity.

Table 9-7: Example of Adaptive Hopping for Higher Order Modulations

Frame ->	**N**	**N+1**	**N+2**	**N+3**	**N+4**	**N+5**	**N+6**	**N+7**
Hop seq 1	M0	M0	M4	M4	M0	M4	M4	M4
	M1	M1	M1	M1	M1	M1	M1	M1
	M2	M2	M2	M2	M6	M6	M6	M6
	M3	M7	M3	M7	M7	M7	M3	M7
Hop seq 2	M4	M4	M0	M0	M4	M4	M0	M0
	M5	M5	M5	M5	M5	M5	M5	M5
	M6	M6	M6	M6	M2	M2	M2	M2
	M7	M3	M7	M3	M7	M3	M7	M3

9.1.1.7 Power Control

Some measure of power control differential between the users supported within the constellation is desirable, in addition to power control for the complete constellation.

A proposal for a modified QPSK constellation was made in [9-9] in order to allow a power differential between 2 users.

As shown in Figure 9-6, for each block of k=4 bits, two of them (b_1 and b_2) are mapped to the sub channel I, and the other two bits (b_3 and b_4) are mapped to the sub channel Q. Because the two sub channels are independent, different protection of the strong bits and weak bits can be obtained by setting a proper value of μ for each sub channel where the distance between the two inner points are denoted by d_i and d_q for the subchannel I and Q, respectively, while the distance between an outer point and its neighbour is denoted by $\mu_i d_i$, and $\mu_q d_q$ for the sub channel I and Q, respectively (μ_i and μ_q are real numbers). In general, μ_q is not necessarily equal to μ_i, and, d_q is not necessarily equal to d_i. These flexibilities make it possible to let all of the four bits have different protection (Note that for $\mu_i = \mu_q$=1.0 and $d_i = d_q$, Figure 9-6 represents a regular 16-QAM constellation with equal distance between all neighboring points.).

In the receiver, the real part and the imaginary part of the received complex symbol can be separated, and a hard decision can be made for each bit following the rules,

$$\hat{b}_1 = \begin{cases} 0 & \text{if } \mathrm{Re}\{r\} > 0 \\ 1 & \text{otherwise} \end{cases} \quad (1)$$

$$\hat{b}_2 = \begin{cases} 0 & \text{if } \left|\mathrm{Re}\{r\}\right| < (\mu_i + 1) d_i / 2 \\ 1 & \text{otherwise} \end{cases} \quad (2)$$

$$\hat{b}_3 = \begin{cases} 0 & \text{if } \mathrm{Im}\{r\} > 0 \\ 1 & \text{otherwise} \end{cases} \quad (3)$$

$$\hat{b}_4 = \begin{cases} 0 & \text{if } \left|\mathrm{Im}\{r\}\right| < (\mu_q + 1) d_q / 2 \\ 1 & \text{otherwise} \end{cases} \quad (4)$$

where $\mathrm{Re}\{r\}$ and $\mathrm{Im}\{r\}$ are the real part and the imaginary part of the received symbol, respectively.

The values of μ_i and μ_q can be estimated in the receiver by observing the received training sequence. Noted that the estimation errors of μ_i and/or μ_q have no effect on the BEP performance of the strong bits; they affect only the weak bits. Furthermore, the estimation errors only widen the performance gap between the strong and weak bits. This effect can be compensated by adjusting the corresponding values of μ_i and/or μ_q accordingly. This method can also be used for adapting μ_i and/or μ_q in response to variation of the channel.

When changing modulation schemes, a number of possibilities can be considered. One is to maintain the carrier power irrespective of modulation. The MSs not in DTX enjoy the improved link performance, although inter cell interference may be increased. This simplifies RSSI measurement within a SACCH multiframe, since all timeslots have the same transmit power. A second option is to transmit the different modulations with a known power differential between them. In this way, similar BEP performance could be possible for the different modulations. However, since the power difference between the modulations is known a priori, the RSSI measurement within a SACCH multiframe can be made as though all slots were transmitted with identical power.

Figure 9-5: Downlink power control on HOM – QPSK

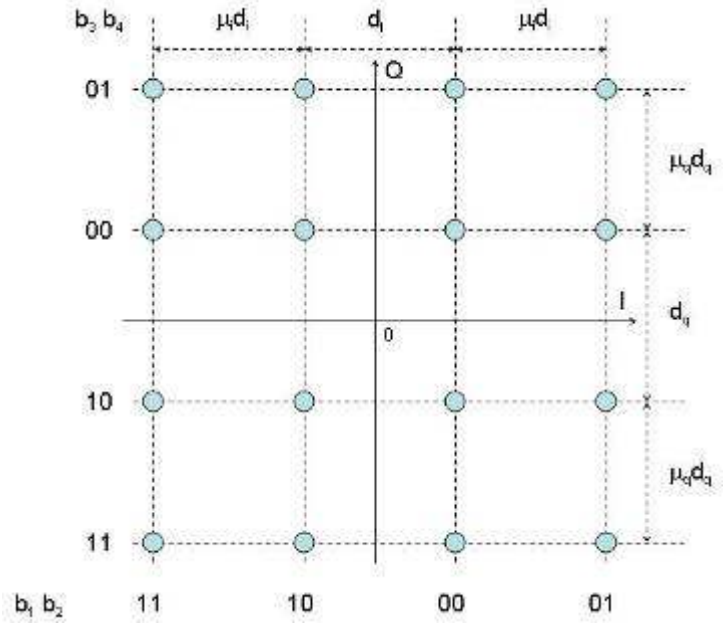

Figure 9-6: Downlink power control on HOM- 16QAM

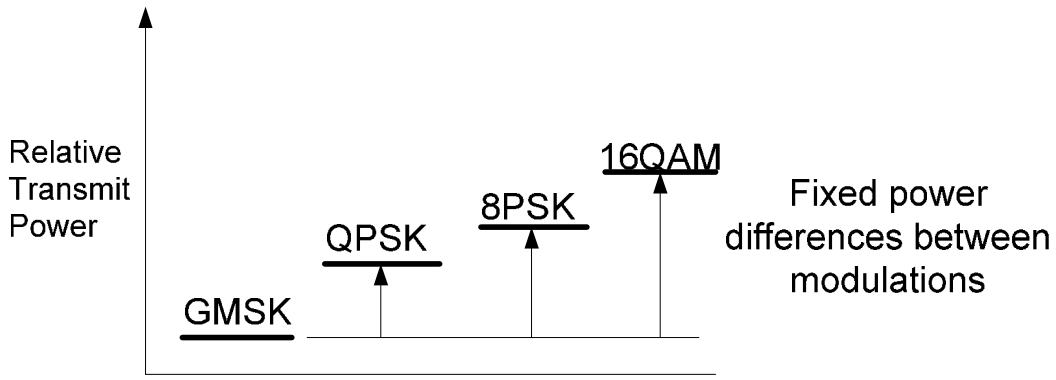

Figure 9-7: Pre-defined Backoff for DTX modulation changes

9.1.1.8 SACCH

The SACCH channels are supported in the following manner. Users M0 and M1 SACCH messages are allocated on frame 12. If both users M0 and M1 are allocated, QPSK modulation is used, such that the first stream S0 is the SACCH of user M0, and the second stream S1 is the SACCH of user M1. If only one user out of M0 and M1 is allocated, GMSK modulation is used for the SACCH of that user. Similarly, the SACCH messages for user M2 and M3 are allocated on frame 25. Note that no modification of the SACCH coding is needed, and no signalling is required.

Repeated SACCH can also be supported using this principle for each user independently.

9.1.1.9 FACCH

FACCH messages are transmitted, as currently, by replacement of the speech frame bits of that user. This ensures the alignment of the FACCH performance to the speech performance. Note that the transmission of FACCH for one of the users does not impact the other users (e.g. no loss of speech frames).

The performance of the FACCH signaling channel should be aligned with the performance of the speech channels that it supports. With the existing channel coding of the FACCH channel, this can be supported over modulations of similar order to those supporting the speech channels. If each speech user is independently encoded, then the bits relating to that user can be replaced by a FACCH block related to that user, without impacting the other users.

Repeated FACCH can also be supported using this principle for each user independently.

9.1.2 Uplink

9.1.2.1 Speech multiplexing

Figure 9-10 shows the concept for uplink MUROS support. For the uplink, up to 2 MSs can co-transmit on the same frequency and timeslot. The users are differentiated by the use of different training sequences. The uplink transmissions can use QPSK modulation or GMSK modulation. In order to achieve the coding rates to support high bit rate codecs like AMR (12.2kb/s), TCH/FS and TCH/EFS, uplink modulation will be QPSK. If one of the MSs is legacy GMSK, then its uplink transmission will be with GMSK modulation.

It is assumed that the BTS uses interference rejection combining (IRC) or successive interference cancellation (SIC) in order to receive the data for each of the users.

In order to support 4 users on the uplink, the allocation can be arranged as shown in Figure 9-11. Two users will be allocated to transmit on each alternate frame. The two user MUROS case is a sub-case of 4 users where the first 2 users are allocated so that they transmit on alternate frames, and co-transmission is avoided until at least 3 users are active.

Note: Co-channel interfered higher order modulation was considered in GERAN Release 7 for DARP Phase II [9-10]. An example requirement in the standard is that, for MCS5, using 8PSK modulation with code rate 0.37, with a GMSK or 8-PSK co-channel interferer, the performance requirement must be met at C/I= -6.5dB. So, it is expected that good

performance with uplink QPSK modulation with a co-channel interferer will be achievable with conditions of a secondary user transmitted so that each user has a C/I around 0dB.

9.1.2.1.1 Legacy Support

Examples of legacy support configurations are shown in Figure 9-12. These different configurations show how full rate or half rate legacy GMSK MSs can be supported on the uplink.

Note that the configurations would allow flexibility such that not all the MSs sharing a physical resource need to be of type full rate or half rate.

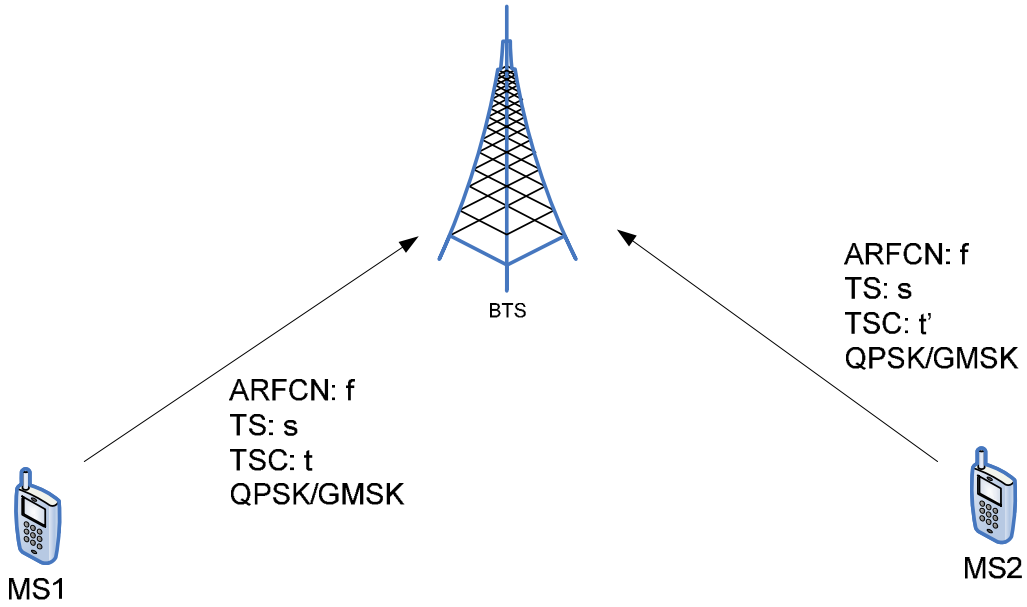

Figure 9-10 : Higher Order Modulation for MUROS in Uplink

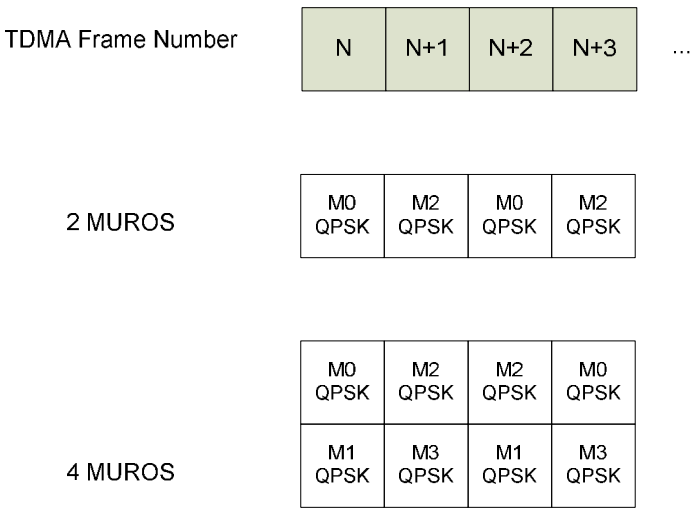

Figure 9-11: Uplink MUROS Configurations

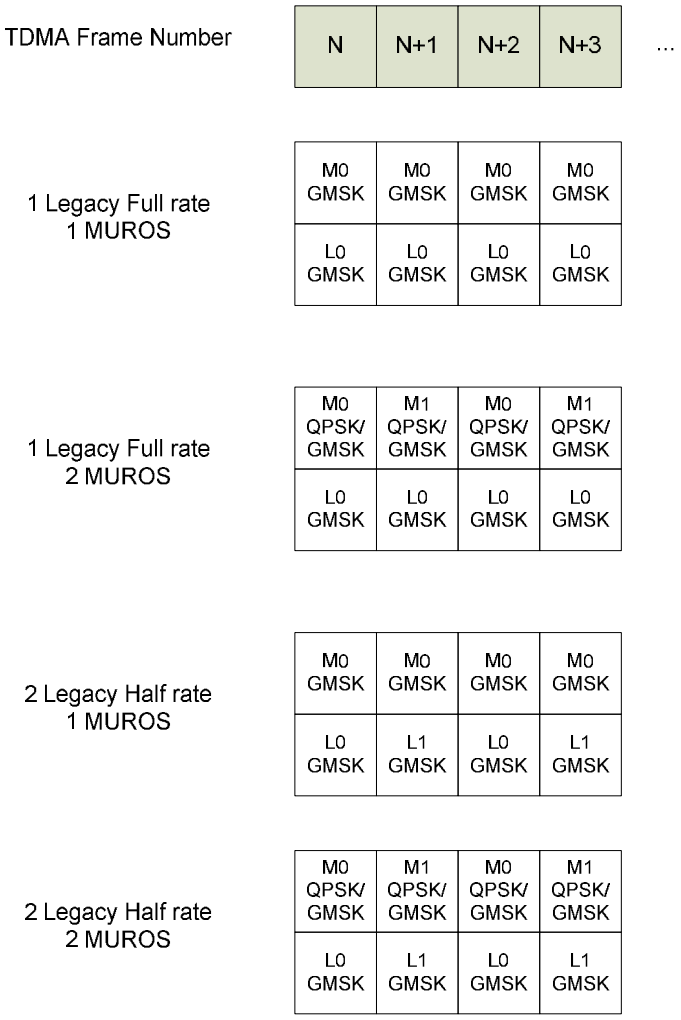

Figure 9-12: Uplink Configurations of MUROS with Legacy

9.1.2.2 Training Sequences

Two QPSK training sequences will need to be defined for normal symbol rate. The base set defined in Table 9-0a for downlink QPSK modulation can be re-used. The second set is based on the GMSK TSC suggested in [9-11] using two diagonal constellation point of QPSK. The results TSC bit sequences are shown in Table 9-7a.

Table 9-7a: Second User QPSK TSC

Training Sequence Code (TSC)	Training sequence
0	0,0,0,0,0,0,1,1,0,0,0,0,0,0,0,1,1,0,0,0,1,1,1,1,0, 0,1,1,0,0,1,1,0,0,0,0,0,0,1,1,1,1,1,1,1,1,0,0,0,0

7	0,0,0,0,1,1,1,0,0,1,1,1,1,1,0,0,0,0,0,1,1,1,1,1,1,1,1,1,1,1,1, 1,0,0,0,0,1,1,1,1,1,1,1,1,1,0,0,1,1,1,0,0,1,1,0,0,0,0

User M0 and M2 are using the TSC listed in Table 9-7a while user M1 and M3 are using the TSC in Table 9-0a.

9.1.2.3 Burst Format Signaling

No burst formatting will be required on the uplink. The users on the same physical uplink resource will be discriminated by the training sequence used by each MS.

9.1.2.4 DTX

Each MS independently transmits on the uplink. When an MS determines that there is no speech on the uplink, the MS does not transmit, except for transmission of the SID and SACCH information.

9.1.2.5 Hopping

As with downlink hopping, adaptive frequency hopping can also be used with the proposed uplink concept, in order to maximize the benefit achievable from MS uplink links entering DTX.

A possible scheme is that shown in Figure 9-13. Eight MSs are shown being supported across the 2 sequences. The example shows a full interleaving sequence of a speech frame. In the first 4 frames MS0 is transmitted on frame N and frame N+3 as one of the two uplink users on hopping sequence 1 in those frames. The second user transmitting on the uplink in each of frame N and frame N+3 is different. Hence, if MS0 uplink is in DTX, both MS1 and MS2 obtain benefit from this. Similarly, MS3 can transmit on frames N+1 and N+2.

In the same way, MS4 and MS7 can transmit on hopping sequence 2.

Note that MS1, MS2, MS5 and MS6 do not move across hopping sequences, and are allocated alternate frames. These MS allocations can be used for 1 or more legacy GMSK MSs. These, of course, would be limited to transmitting GMSK modulation on the uplink timeslots.

In terms of allocation of MSs, it is of course preferable to allocate them initially so that they are not transmitting on the same frames, and only once this has been completed, to start allocating the second of the pairs (e.g. {MS0, MS1}).

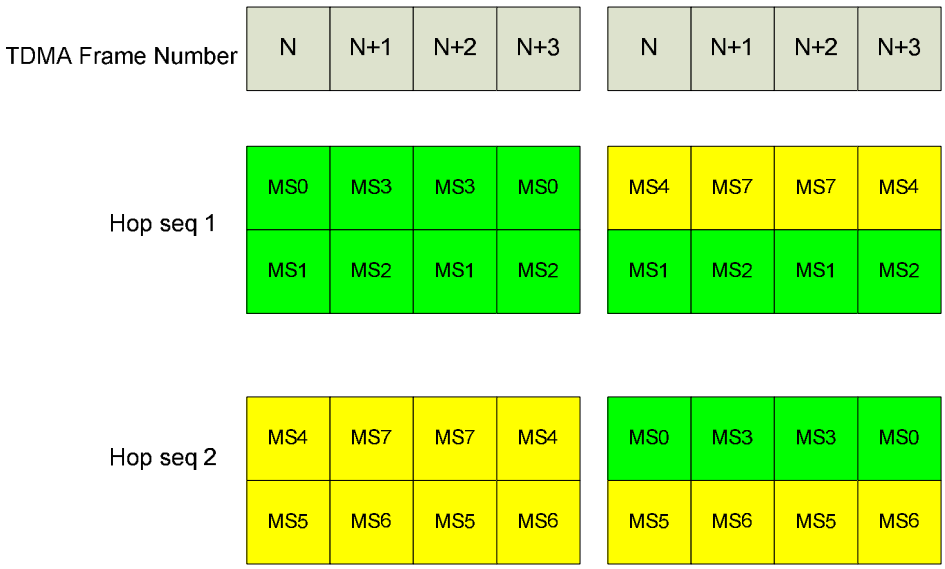

Figure 9-13: Hopping across 2 hopping sequences on Uplink

9.1.2.6 Codecs support and Achievable Code Rates

The code rates achievable with multiplexing a speech user over a QPSK modulation with interleaving depth of 4 slots is the same as is achievable for TCH/AFS over GMSK. So the achievable code rates are given in Table 9-1 above.

9.1.2.7 Power Control

On the uplink, each uplink independently transmits. The power requested by the network is set for each MS, such that two users" transmissions can be reliably separated.

9.1.2.8 SACCH

The SACCH channels are supported in the following manner. Each user transmits its SACCH channel using GMSK modulation, as per legacy. Users M0 and M1 are allocated on frame 12, and users M2 and M3 are allocated on frame 25. Note that no modification of the SACCH coding is needed, and no signalling is required.

Repeated SACCH can also be supported using this principle for each user independently.

9.1.3 Dynamic Channel Allocation

In addition to some internal power control, dynamic channel allocation (DCA), can group the users into sets of users that have similar needs, and allocate these to a common resource. As the signal conditions of each user change, these sets can be updated in order to maximize effectiveness.

9.2 Performance Characterization

9.2.1 Link Level Performance

9.2.1.1 Sensitivity Performance

This section shows the performance of the different speech codecs in sensitivity conditions.

In each plot, the sensitivity performance of the speech channel is shown for relevant physical channel. Lines are shown for 1 user (black), 2 users (blue), 3 users (green) and 4 users (red). For the case of 3 and 4 co-allocated users, 2 curves are shown, corresponding to mapping of the stream to strong bits or weak bits in the modulation constellation. For 3 users, 2 streams are on strong bits, and one on weak bit stream. For 4 users, 2 users are on each of the strong and weak bits.

Table 9-7b: Simulation Assumptions for sensitivity performance evaluation

Parameter	Value
Speech codec	TCH/AFS5.9, TCH/AFS12.2, TCH/AHS5.9, TCH/FS, TCH/FS, TCH/EFS
Channel profile	TU3, TU50
Frequency band	900 MHz
Frequency hopping	Ideal
Interference	Sensitivity
Backoff	GMSK 0dB QPSK 2.2dB 8PSK 3.3dB 16-QAM 4.4dB
No. simulated speech frames	10, 000

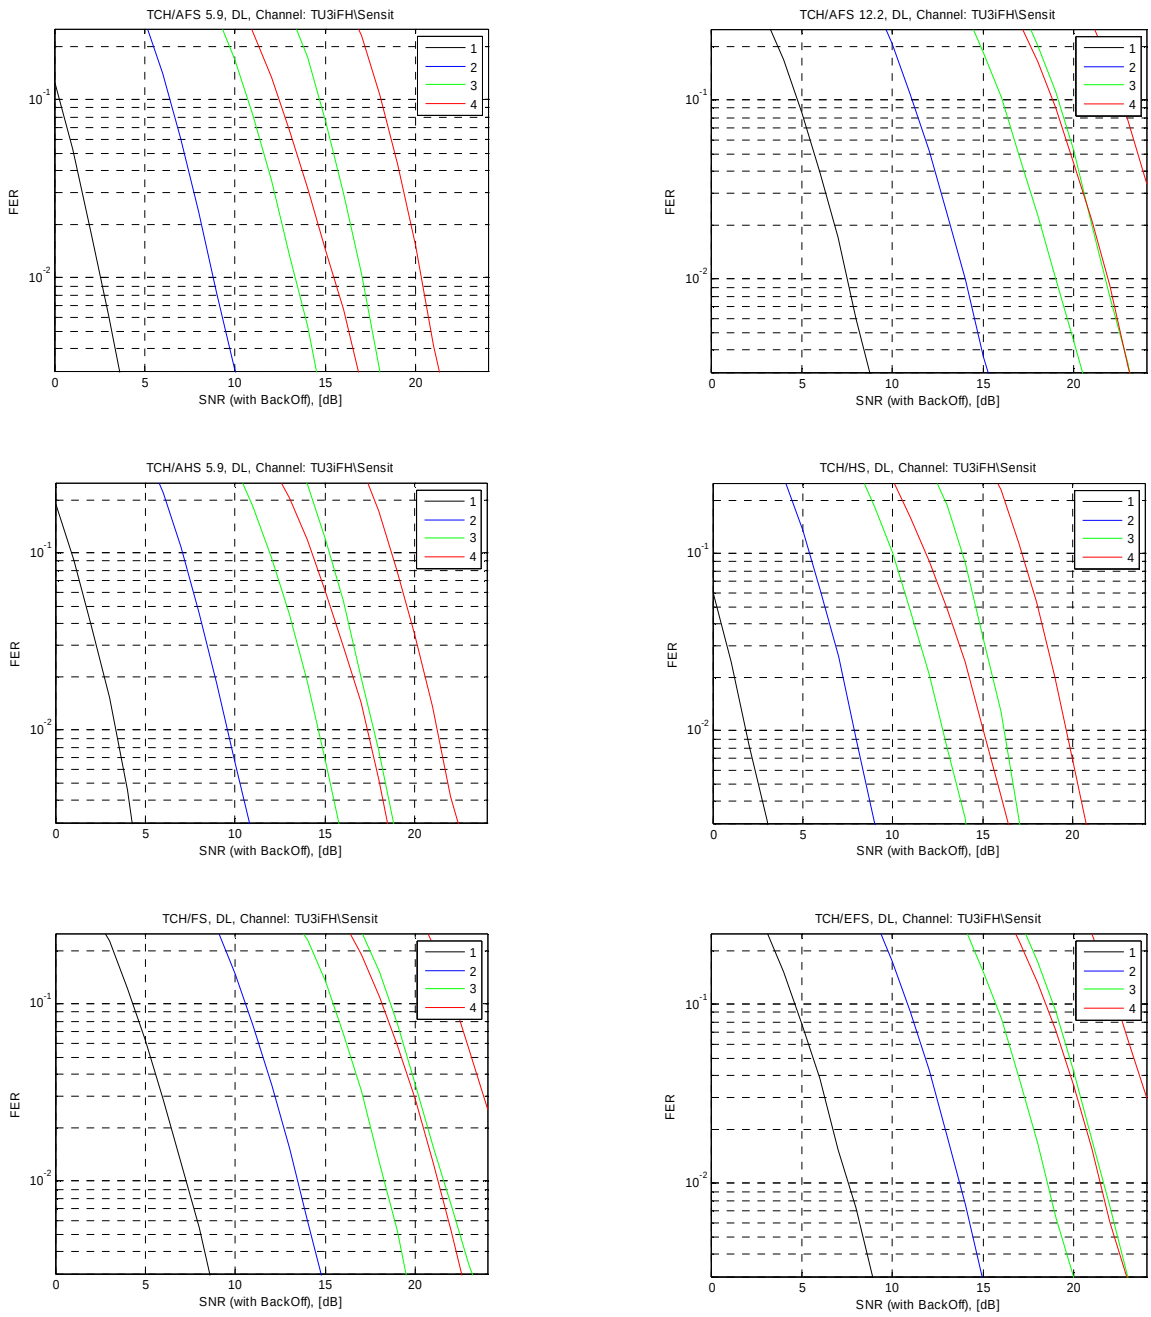

Figure 9-13a: Multiplexed users in DL, Sensitivity/TU3iFH

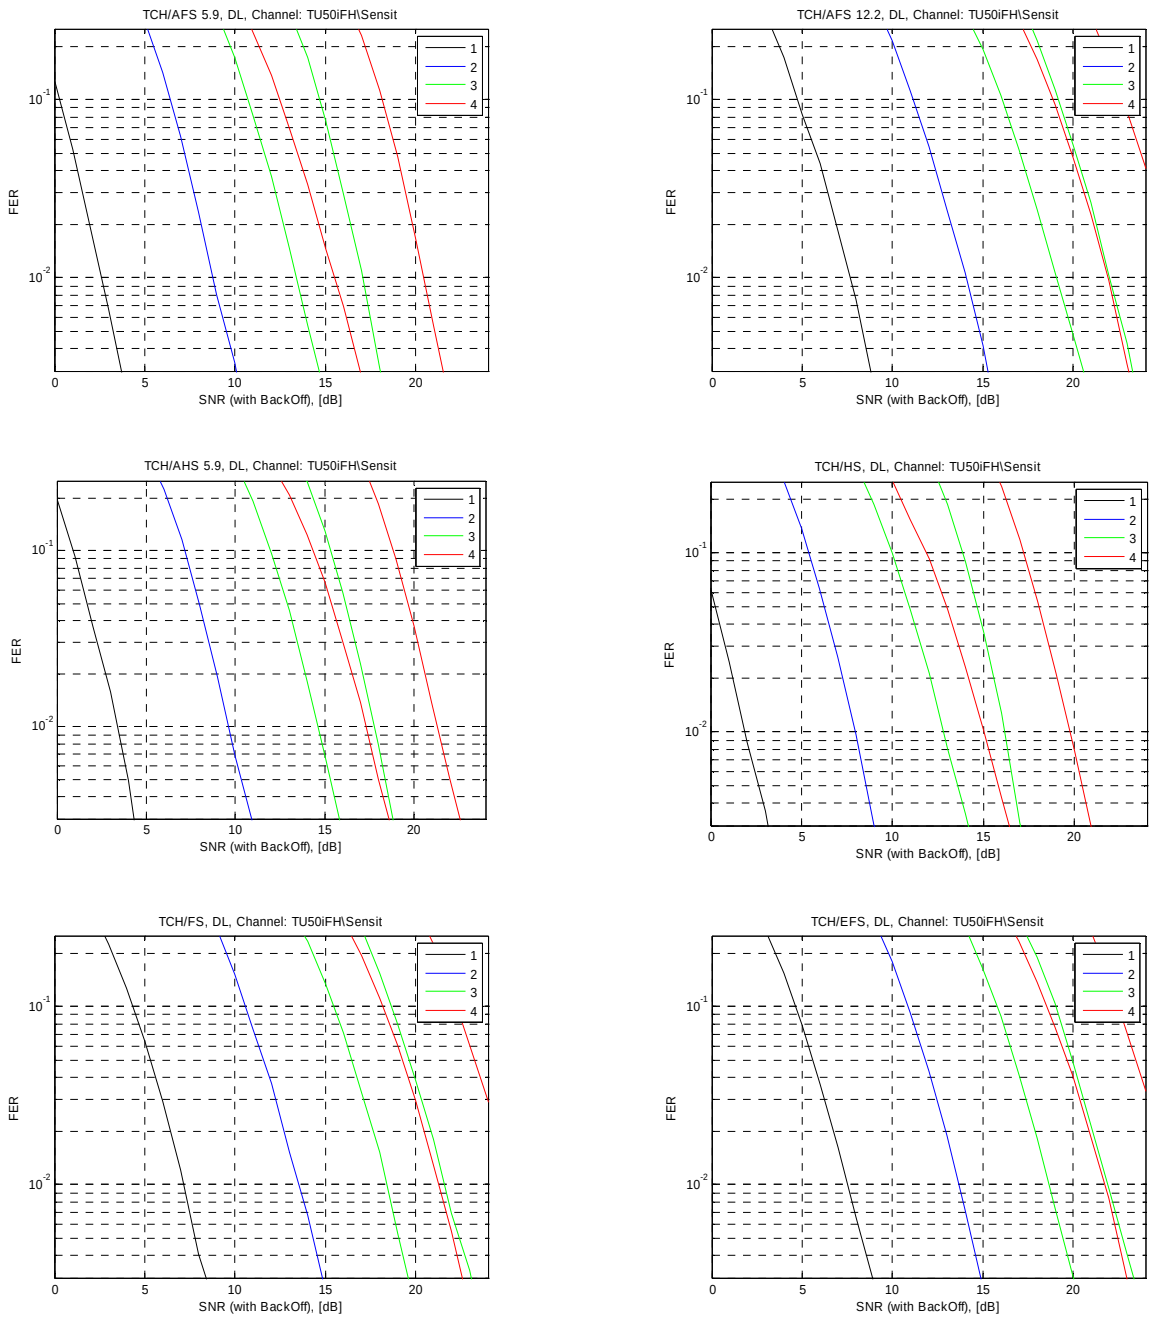

Figure 9-13b: Multiplexed users in DL, Sensitivity/TU50iFH

9.2.1.2 Interference Performance

9.2.1.2.1 Co-channel Performance

This section shows simulation results for two speech users multiplexed on QPSK modulation both in uplink and downlink, and four speech users multiplexed on 16-QAM modulation both in uplink and downlink. The conditions are co-channel interferer with a TU3 iFH channel. For two all users and four users, the legacy AMR coding schemes and puncturing were used.

Figure 9-14 shows the downlink performance achievable with the AMR 5.9kbps codec for 2 and 4 users, as compared to the legacy single user 5.9kbps case. Also shown are the 45.005 requirements for TCH/AFS12.2, TCH/AFS5.9 and TCH/AHS5.9. The 2 user MUROS curve only requires a 1.2dB improvement over the single user legacy case; it also exceeds the TCH/AFS5.9 requirement in 45.005 by around 3dB. The 4-user MUROS case exceeds the TCH/AHS5.9

requirements by around 2dB. That is, with a 2dB degradation in C/I, double the number of speech users can be supported as compared to the legacy requirements.

Figure 9-15 shows the downlink performance achievable with the AMR 12.2kbps codec for 2 and 4 users, as compared to the legacy single user 12.2 kbps case. Similarly to the 5.9 case, the 2-user MUROS case using the12.2kbps codec only requires a 0.5dB improvement over the single user legacy case. The 4-user MUROS case can also be supported with a C/I=15.5dB which, based on network measurements done during Release 7 GERAN Evolution work, is very reasonable to occur in networks.

Figure 9-16 shows the downlink performance for the case when only a half rate traffic physical channel is allocated to MUROS users, as for instance when the other half rate is allocated to legacy usage. The performance of 2-user MUROS carrying AMR5.9kbps is compared to TCH/AFS5.9 and TCH/AHS5.9 performance. Also shown are the 45.005 requirements for TCH/AHS5.9. It can be seen that an improvement of only 0.5dB is needed to support 2 users over the half rate resource. Also, the MUROS performance exceeds the TCH/AHS5.9 performance requirement by 1dB. So, allocating part of the resource to a legacy user, does not affect the ability to use the remainder of the resource in an effective way for MUROS.

9.2.1.2.2 MTS-x Performance

This section shows the performance of speech over the defined MUROS channels, under the different types of MUROS interferers that could be present. That is, GMSK, QPSK and 16QAM interferers. Simulations are shown for configurations MTS-1 to MTS-4.

In the Figures 9-17 to 9-24, the line colour indicates the number of users, 1, 2 or 4, and the shape indicates the interferer type. Also shown by the purple and green markers are 3GPP standard requirements of a number of cases.

Table 9-8 Simulation Assumptions for MTS-x performance evaluation.

Parameter	Value
Speech codec	AMR 5.9 and 12.2
Channel profile	TU3
Frequency band	900 MHz
Frequency hopping	Ideal
Interference	MTS-1, MTS-2, MTS-3, MTS-4 (GMSK, QPSK, 16QAM)
Receiver type	Conventional
Rx filter	Conventional

9.2.1.2.3 Co-Channel Performance with Power Control

This section shows the range of power control available in the higher modulations by use of mapping the user streams to the different strength bits in the modulation constellation, as described earlier. In addition, this can also be enhanced by modification of the constellation as proposed in Section 9.1.1.7.

The following Figures are shown for the 12.2 and 5.9 AMR full rate codecs, in channel scenarios MTS-1 to MTS-4 with MUROS interference. For 2 users over QPSK, a single line is shown as both bits in the constellation are of same strength. For 3 users over 8-PSK, 2 lines are shown – 2 users are with strong bits, 1 with less strong. For 4 users over 16-QAM, 2 lines are shown – 2 users with strong bits, 2 users with less strong. Additionally, markers indicate 45.005 standard requirements where relevant. It can be seen that performance of 3 and 4 users is quite similar. It can also be seen that by simple mapping, it is possible to support speech users in conditions that are only 6dB worse than legacy speech channels.

9.2.1.4 Adjacent Interference Performance

[to be included]

9.2.2 Network Level Performance

[tbd]

9.3 Impacts on the Mobile Station

The presented concept is compatible with legacy MSs. Legacy MS designs that already support modulations required for Release 7 require the following changes

- Support of new multiplexing schemes for multiuser speech
- Definition of new training sequences, both on downlink and uplink
- Signaling support to indicate new MS capabilities
- Modification of modulation definitions to support QPSK on uplink (at Normal Symbol Rate)

Legacy MSs that support only GMSK modulation are supported

- Multiplexing on a QPSK modulation with π/2 constellation rotation, and use of a legacy training sequence on the sub-channel
- Multiplexing of legacy MS on dedicated timeslot

9.4 Impacts on the BSS

- Support of new multiplexing schemes for multiuser speech channels
- Support of QPSK Normal Symbol Rate reception
- Signaling support to indicate channel status

9.5 Impacts on Network Planning

There should be no impacts on network planning, as the multiplexing schemes take advantage of existing excess C/I available in current typical network layouts.

9.6 Impacts on the Specification

The following specification documents are expected to be updated

Specification	Comments
24.008	Capability indication for HOM/MUROS
44.018	RR support for HOM/MUROS
45.002	Definitions of multiple users on MUROS channels
45.003	Channel coding definitions to support HOMUROS
45.004	Modulation definition for QPSK on uplink; QPSK with π/2 rotation on downlink
45.005	Performance requirements for new HOM/MUROS channels
45.008	Link quality measurements

9.7 Summary of Evaluation versus Objectives

In this section the candidate technique is evaluated against the defined objectives in chapter 4. Note, this section represents the view of the proponents of this candidate technique.

The following classification is used for the evaluation:

Fulfilled

Expected to be fulfilled

Unclear/FFS

Not fulfilled

9.7.1 Performance Objectives

Evaluation of MUROS Candidate Techniques **Performance Objectives**	**Higher Order Modulation**
P1: Capacity Improvements at the BTS 1) increase voice capacity of GERAN in order of a factor of two per BTS transceiver 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Network simulations have not yet been presented to show the available spectral efficiency gain
	2) All codecs are supported.
P2: Capacity Improvements at the air interface 1) enhance the voice capacity of GERAN by means of multiplexing at least two users simultaneously on the same radio resource both in downlink and in uplink 2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	1) Up to 4 users are multiplexed on the same radio resource
	2) All codecs are supported.

9.7.2 Compatibility Objectives

Evaluation of MUROS Candidate Techniques **Compatibility Objectives**	**Higher Order Modulation**
C1: Maintainance of Voice Quality 1) voice quality should not decrease as perceived by the user. 2) A voice quality level better than for GSM HR should be ensured.	1) Only users experiencing good enough quality will be allocated on a multiuser channel
	2) Minimum FER thresholds have been defined in the TR. Given the same FER level, the voice quality for any of the defined codecs exceeds that for GSM HR.
C2: Support of Legacy Mobile Stations 1) Support of legacy MS w/o implementation	1) Legacy, DARP Phase I, mobiles can be supported on the first sub channel by 2-user allocation on a resource.

impact. 2) First priority on support of legacy DARP phase 1 terminals, second priority on support of legacy GMSK terminals not supporting DARP phase 1.	2) Legacy non DARP Phase I terminals can be supported on the first sub channel by 2-user allocation on a resource.
C3: Implementation Impacts to new MS's 1) change MS hardware as little as possible. 2) Additional complexity in terms of processing power and memory should be kept to a minimum.	1) Legacy MSs supporting downlink 16-QAM (Rel-7 EGPRS2) can be multiplexed for up to 4 users on a resource. Legacy MSs supporting downlink 8-PSK can be multiplexed for up to 3 users on a resource.
	2) New multiplexing of users on timeslot data. New QPSK training sequences (possible also to use proposed sequences). QPSK modulation on uplink – this is a subset of 8PSK for EDGE capable MS.
C4: Implementation Impacts to BSS 1) Change BSS hardware as little as possible and HW upgrades to the BSS should be avoided. 2) Any TRX hardware capable for MUROS shall support legacy non-SAIC mobiles and SAIC mobiles. 3) Impacts to dimensioning of resources on Abis interface shall be minimised.	1) Legacy BTS capable of 8PSK downlink modulation allows up to 3 users multiplexed on a resource, using 16QAM. Legacy BTS capable of 16QAM downlink modulation (already supported on by Rel 7 EDGE2), allows up 4 users multiplexed on a resource. New QPSK training sequences on uplink. New multiplexing of users on timeslot data Demodulation of two simultaneous signals is needed.
	2) The concept has no impact on the support of different types of mobiles for the TRX
	3) Impact is to reserve a higher number of sub channels on Abis interface and possibly use another packet Abis technology.
C5: Impacts to Network Planning 1) Impacts to network planning and frequency reuse shall be minimised. 2) Impacts to legacy MS interfered on downlink by the MUROS candidate technique should be avoided in case of usage of a wider transmit pulse shape on downlink. 3) Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator"s band allocation and in country border regions where no frequency coordination are in place.	1) No impact on frequency planning or frequency re-use is foreseen.
	2) Impacts on legacy MS reception for optimised TX pulse shape would require further investigation
	3) Optimised TX pulse shape is not expected to be used at band edge or at the edge of an operator's allocation.

10 New Training Sequences

A number of candidate techniques using a new set of training sequences were proposed for speech capacity enhancement under MUROS study item. In total 7 different sets of new training sequences were proposed. These are enumerated in this section.

10.1 Training sequence candidates proposed

10.1.1 TSC Set proposed by Nokia [10-1]

10.1.9 TSC S

Table 10-9: Motorola candidate training sequence symbols-2

10.2 Training sequence evaluation and selection

The criteria for selection of TSC"s were agreed at GERAN#39:

- Legacy TSC is used on 1st subchannel
- New proposed TSC is used on 2nd subchannel
- Performance of TSC pairs is evaluated
- Restriction to single interferer scenario MTS-1 with the interferer either using GMSK or MUROS modulation type.
- Both DL and ULwill be evaluated.
- Evaluate in addition the cross correlation performance of new TSC"s whilst the evaluation method is left open [7]

[7] This additional criterion has been defined in MUROS telco #6 [10-8].

At GERAN 1 Adhoc on EGPRS2/WIDER/MUROS following agreements were achieved:

- fixed pairs will be used for the training sequence evaluation. There was no agreement to standardise training sequence pairs.
- newly proposed TRS sets will be included in the TR but without corresponding performance simulation results (in order not to overload the TR).
- selection could wait until after a WI is opened.
- no new proposal for new training sequences will be accepted from this point in time, unless it was shown to provide a significant performance improvement of (~0.5 dB).

At MUROS telco#7 following agreements were achieved:

- Contributions can be provided by companies to check the cross correlation properties of unpaired sequences at GERAN#40.
- Voting will be used at GERAN#40 to select the best sequence among the candidate sets.

At GERAN#40 it was agreed to freeze the work related to the evaluation of the best TSC set, until a work item is started. Hence further training sequence evaluation as well as final selection of the TSC set will take place within the sucessive work item VAMOS.

11 Associated Control Channel Design

11.1 Shifted SACCH

11.1.1 Introduction

In the document[11-1], the link level simulation results show that legacy SACCH transmission method with OSC could not meet the performance requirements for SACCH. In this contribution a new strategy on SACCH is proposed. The link level performances of the new strategy are also provided.

11.1.2 Concept description

The basic idea of this new approach is described as follows. Figure 11-1 shows the legacy and new TDMA frame mapping for TCH/HS and SACCH/HS. For example, there are 4 users (u1~u4) reusing 2 HR channels. U1 and u2 are legacy mobiles using the legacy TDMA mapping. U3 and u4 are two MUROS mobiles using the new TDMA mapping. U1 and u3 are two paired users in one HR channel. U2 and u4 are two paired users in the other HR channel. In the new TDMA frame mapping, the two SACCHs are mapping to the 6th and the 18th frame in a 26-multiframe. They are mapping to the 12th and 25th frame in the legacy TDMA mapping. Then the two paired users have different SACCH locations. In order to improve the performance of SACCH, it can increase the transmission power level of SACCH and decrease the transmission power level of the corresponding TCH for the paired user. With the same total transmission power level of the HR channel it can get better performance of SACCH and little influence of TCH performance. In the new strategy on SACCH for MUROS, the TCH/HS mapping rule has a little change. It is not alternate one after another any more when extracting SACCH. This arrangement ensures the paired relationship of the two users.

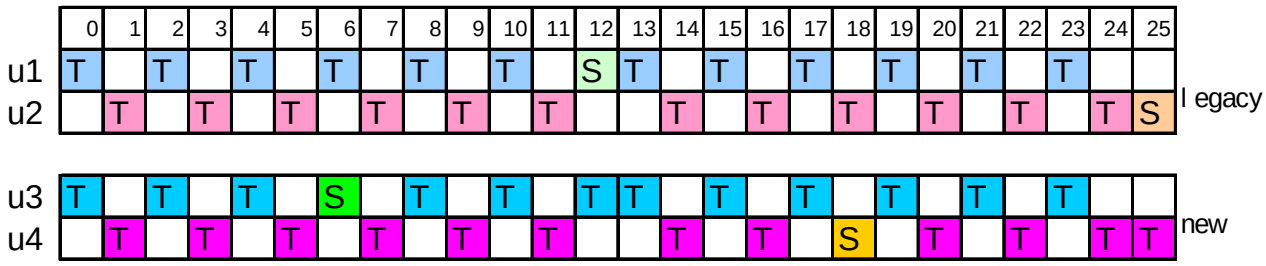

Figure 11-1 TDMA frame mapping for TCH/HS + SACCH/HS, legacy and new

11.1.3 Simulation Results

11.1.3.1 Simulation assumptions

The simulation assumptions are shown in Table 11-1.

Table 11-1 Simulation assumptions of link performance

Parameter	Value
Propagation Environment	Typical Urban (TU)
Terminal speed	50 km/h
Frequency band	900 MHz
Frequency hopping	No
Interference/noise	MTS-1, MTS-2
Antenna diversity	No
DARP receiver	VAR receiver
Tx pulse shape	legacy linearized GMSK pulse shape
Trainning sequence	Existing sequence and new sequence proposed in [11-2]
Channel type	SACCH using MUROS TCH AHS5.9 using MUROS
Interference modulation type	GMSK

11.1.3.2 SACCH MUROS performance in MTS-1

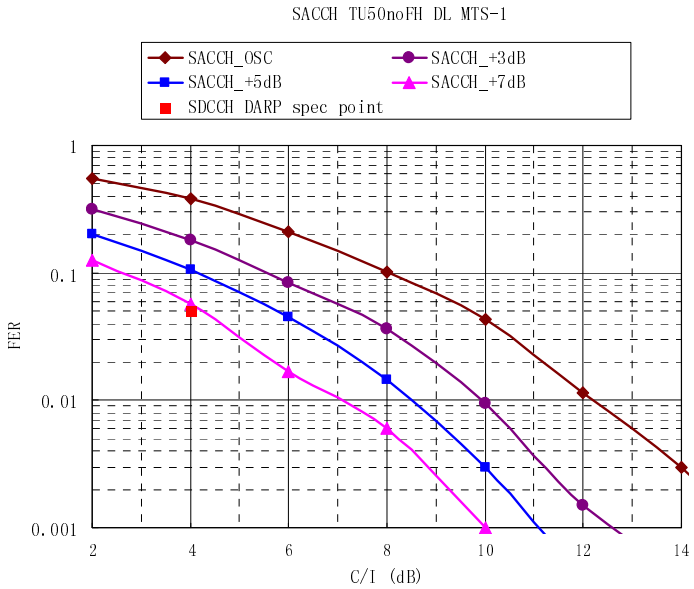

Figure 11-2: MUROS DL interference performance SACCH, MTS-1

11.1.3.3 SACCH MUROS performance in MTS-2

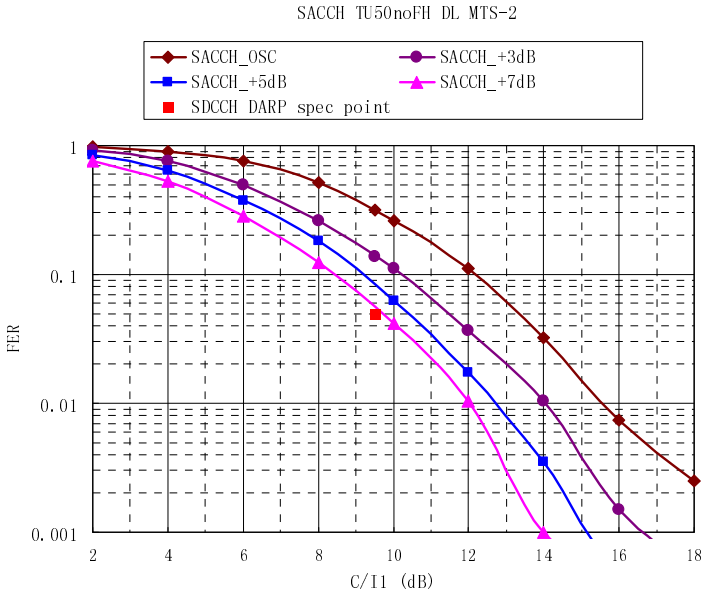

Figure 11-3: MUROS DL interference performance SACCH，MTS-2

11.1.3.4 TCH/AHS5.9 MUROS performance in MTS-1

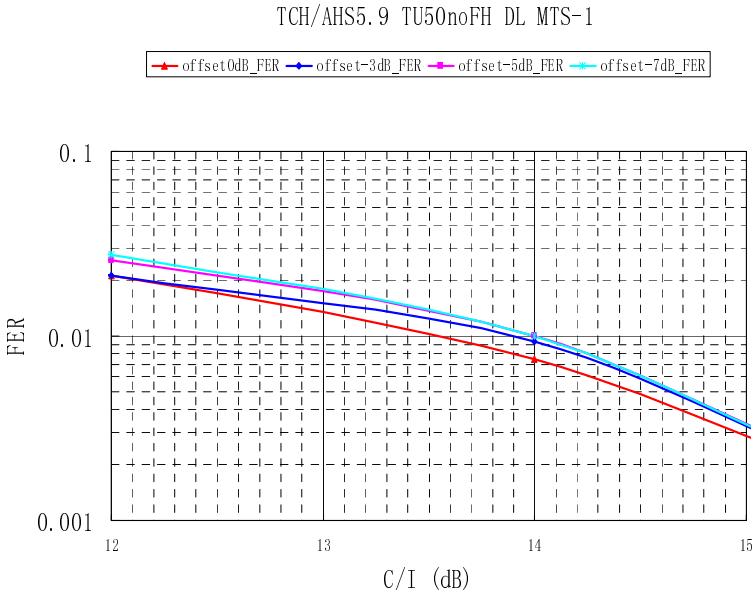

Figure 11-4: MUROS DL interference performance TCH/AHS5.9, MTS-1

11.1.3.5 TCH/AHS5.9 MUROS performance in MTS-2

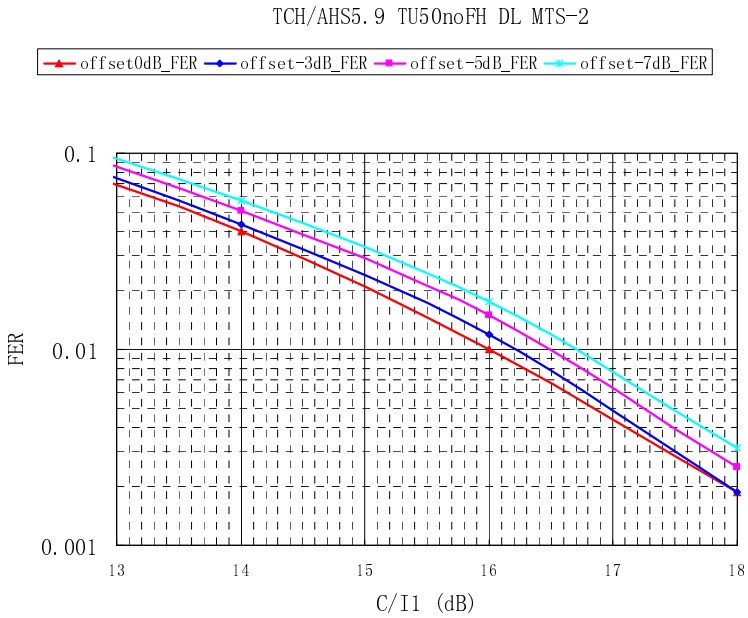

Figure 11-5: MUROS DL interference performance TCH/AHS5.9, MTS-2

11.1.3.6 Link performance analysis

Figure 11-2 and Figure 11-3 show the simulation results of link level interference performance for SACCH with different power offset. Figure 11-4 and Figure 11-5 give the results of TCH/AHS5.9. In a brief summary, Table 11-2 and Table 11-3 provide the absolute value of C/I1 at FER=1% and the gain or loss relative to 0dB power offset situation.

Table 11-2: SACCH DL link level interference performance @FER=1%

power offset	MTS-1		MTS-2	
	absolute value (dB)	Gain (dB)	absolute value (dB)	Gain (dB)
0dB	12.2	0	15.6	0
+3dB	10	2.2	14	1.6
+5dB	8.5	3.7	12.8	2.8
+7dB	7	5.2	12	3.6

Table 11-3: TCH/AHS5.9 DL link level interference performance @FER=1%

power offset	MTS-1		MTS-2	
	absolute value (dB)	Loss (dB)	absolute value (dB)	Loss (dB)
0dB	13.5	0	16	0
-3dB	13.9	0.4	16.2	0.2
-5dB	14	0.5	16.5	0.5
-7dB	14	0.5	16.7	0.7

From all the results, it can be seen that the performance of SACCH is improved through the overpower method. When the power offset up to 7dB, the performance of SACCH can get about 5.2dB gain. It could nearly meet the requirements in 45.005. And at the same time, the performances of TCH get a little influence with lower power transmission. The loss is less than 0.7dB.

11.1.4 Conclusion

This contribution has studied a new strategy on SACCH for downlink MUROS. The simulation results are also provided with the new method. By means of the new strategy, it can get better performance of SACCH and reasonable performance of TCH.

12 Summary of Evaluation versus Objectives for each Candidate Technique

A number of candidate techniques have been proposed for MUROS and have been included in this Technical Report. This section lists a summary of the evaluation versus the defined performance and compatibility objectives in section 4 for each of the proposed candidate techniques.

12.1 Performance Objectives

Table 12-1: Evaluation against performance objectives

Performance Objectives	Co-TCH	Orthogonal Sub Channels	Adaptive Symbol Constellation	Higher Order Modulation
P1: Capacity Improvements at the BTS 1) increase voice capacity of GERAN in order of a factor of two per BTS transceiver	1) Two users are multiplexed on the same BTS resources. For some BTS architectures there might not be a HW efficiency gain.	1) Two users are multiplexed on the same BTS resource both in uplink and downlink.	1) Two users are multiplexed on the same BTS resource.	1) Up to 4 users are expected to be multiplexed per timeslot.
2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	2) All voice codecs are supported	2) All codecs are supported.	2) All codecs are supported	2) All codecs are supported.
P2: Capacity Improvements at the air interface 1) enhance the voice capacity of GERAN by means of multiplexing at least two users simultaneously on the same radio resource both in downlink and in uplink	1) Gains have been shown to be between 0 and 125 % depending on the system scenario and speech codec.	1) Gains have been shown by system level simulations on DL to be between 0% and 76% in GP-081632 dependent on the system scenario and speech codec investigated for OSC. Gains versus reference on top have been shown when utilizing sub channel specific power control in the range of 7% to 16%. Further gains may be possible by the usage of optimized Tx pulse shape on DL.	1) Gains have been shown to be between 0 and 114 % dependent on the system scenario and speech coded investigated for OSC. Gains in the range of 5..13% on top have been observed for adaptive constellation rotation used for new MUROS capable MS. Further enhancements may be possible when utilizing α-QPSK and frequency hopping.	1) Network simulations have not yet been presented to show the available spectral efficiency gain
2) channels under interest: TCH/FS, TCH/HS, TCH/EFS, TCH/AFS, TCH/AHS and TCH/WFS	2) All speech codecs are supported	2) All codecs are supported.	2) All codecs are supported	2) All codecs are supported.

12.2 Compatibility Objectives

Table 12-2: Evaluation against compatibility objectives

Evaluation of MUROS Candidate Techniques	Candidate Techniques proposed in MUROS			
Objective	Co-TCH	Orthogonal Sub Channels	Adaptive Symbol Constellation	Higher Order Modulation for MUROS
Compatibility Objectives				
C1: Maintainance of Voice Quality 1) voice quality should not decrease as perceived by the user. 2) A voice quality level better than for GSM HR should be ensured.	Fulfilled. 1) It is assumed that channel mode adaptation (CMA) takes place if quality in co-TCH channel degrades. Link performance and system performance evaluations have confirmed that there is no voice quality decrease. 2) Minimum FER thresholds have been defined in the TR, that have been evaluated by system level analysis. References: see performance characterization in chapter 6.	Fulfilled. 1) It is assumed that channel mode adaptation (CMA) takes place if quality in OSC channel degrades. Link performance and system performance evaluations have confirmed that there is no voice quality decrease. have confirmed that there is no voice quality decrease. 2) Minimum FER thresholds have been defined in the TR, that have been taken into account in system level analysis. References: see performance characterization in chapter 7.	Fulfilled. 1) It is assumed that channel mode adaptation (CMA) takes place if quality in alpha-QPSK channel degrades. Link performance and system performance evaluations have confirmed that there is no voice quality decrease. 2) Minimum FER thresholds have been defined in the TR, that have been taken into account in system level analysis. References: see performance characterization in chapter 8.	Fulfilled. 1) It is assumed that channel mode adaptation (CMA) takes place if quality in HOM for MUROS channel degrades. Link level evaluations have confirmed that there is no voice quality decrease. Link performance performance have confimed that there is no voice quality decrease. 2) Minimum FER thresholds have been defined in the TR, that have been taken into account in system level analysis. References: see performance characterization in chapter 9.
C2: Support of Legacy Mobile Stations 1) Support of legacy MS w/o implementation impact. 2) First priority on support of legacy DARP phase 1 terminals, second priority on support of legacy GMSK terminals not supporting DARP phase 1.	Fulfilled. 1) With power assignment procedure in DL, both legacy non-DARP MS and legacy-DARP phase I MS are expected to be multiplexed. 2) Legacy DARP phase I terminals have been shown to be supported with the technique. Non DARP terminals could be supported under fairly good radio conditions.	Fulfilled. 1) With subchannel power control procedure in DL, both legacy non-DARP MS and legacy-DARP phase I MS are expected to be multiplexed. 2) Legacy DARP phase I terminals have been shown to be supported with the technique. Non DARP terminals could be supported under fairly good radio conditions.	Fulfilled: 1) With downlink powr control using alpha-QPSK, both legacy non-DARP MS and legacy-DARP phase I MS are expected to be multiplexed. pi/4 rotation is not compatible with legacy mobiles. 2) Legacy DARP phase I terminals have been shown to be supported with the technique. Non DARP terminals could be supported under fairly good radio conditions. Evaluations show capacity gains with non-DARP mobiles included in MUROS channels.	Unclear/FFS 1) With downlink power control using QPSK, both legacy non-DARP MS and legacy-DARP phase I MS are expected to be multiplexed for up to 2 users. Whilst 3 or 4 user allocation is not compatible with legacy mobiles. 2) Non DARP terminals need to be studied at link and system level.
C3: Implementation Impacts to new MS's 1) change MS hardware as little as possible. 2) Additional complexity in terms of processing power and memory should be kept to a minimum.	1) Minimum requirement is to support new training sequences. Impact of new training sequences on complexity and memory requirements is minimal. 2) More advanced receiver implementations, such as joint detection, can improve performance and this will have impact on complexity and memory. Adaptive pulse shaping may lead to additional complexity.	1) Minimum requirement is to support new training sequences. Impact of new training sequences on complexity and memory requirements is minimal. 2) More advanced receiver implementations, such as joint detection, can improve performance and this will have impact on complexity and memory. For OSC only 3 different constellations are defined which may mitigate the additional complexity. User diversity scheme proposed needs additional timeslot hopping functionality.	1) Minimum requirement is to support new training sequences. Impact of new training sequences on complexity and memory requirements is minimal. Additional rotation (note that blind modulation detection algorithms from EGPRS can be re-used) need to be supported and blindly detected by the mobile. 2) More advanced receiver implementations, such as joint detection, can improve performance and this will have impact on complexity and memory. Detection of one additional rotation might add complexity and can be done in the same way as in modulation detection in EGPRS. Estimation of alpha is slightly more complex than the detection of one additional rotation. Frequency hopping scheme proposed needs additional frequency hopping sequences.	1) Higher order modulations need to be supported in downlink. The impact is likely similar to that of EGPRS2-A. It requires new user multiplexing. New uplink transmission scheme other than GMSK needed. Additional complexity introduced because of the downlink power control.
C4: Implementation Impacts to BSS 1) Change BSS hardware as little as possible and HW upgrades to the BSS should be avoided. 2) Any TRX hardware capable for MUROS shall support legacy non-SAIC mobiles and SAIC mobiles. 3) Impacts to dimensioning of resources on Abis interface shall be minimised.	Expected to be fulfilled. 1) Depending on the implementation, 2 GMSK modulators or a flexible quarternary constellation based modulator is required on the transceiver. Adaptive pulse shaping needs additional complexity. JD or SIC for GMSK receiver needed. 2) For EDGE capable BTS this is usually the case. 3) The capacity of the Abis interface needs to be increased by up to a factor of 2 compared to full rate channels.	Expected to be fulfilled. 1) No BTS HW change required in the transmitter, since QPSK and 8-PSK are supported on EDGE capable BTS. JD or SIC for GMSK receiver needed. 2) For EDGE capable BTS this is usually the case. 3) The capacity of the Abis interface needs to be increased by up to a factor of 2 compared to full rate channels.	Expected to be fulfilled 1) Linear modulator for alpha-QPSK, additional rotation needed. JD or SIC for GMSK receiver needed. 2) For EDGE capable BTS this is usually the case. The support of Frequency hopping proposal depends on BTS architecture. 3) The capacity of the Abis interface needs to be increased by up to a factor of 2 compared to full rate channels.	Unclear/FFS 1) Higher order Modulation transmitter needed as for EGPRS2-A. JD/SIC receiver capable of receiving upto 2 QPSK users simultaneously on the uplink needed. BTS needs enough processing power to demodulate GMSK or QPSK on up to 4 different resources simultaneously on uplink. 2) This depends on BTS architecture. 3) The capacity of the Abis interface needs to be increased by up to a factor of 4 compared to full rate channels.
C5: Impacts to Network Planning 1) Impacts to network planning and frequency reuse shall be minimised. 2) Impacts to legacy MS interfered on downlink by the MUROS candidate technique should be avoided in case of usage of a wider transmit pulse shape on downlink. 3) Furthermore investigations shall be dedicated into the usage at the band edge, at the edge of an operator's band allocation and in country border regions where no frequency coordination are in place.	Expected to be fulfilled. 1) No impact on frequency planning or frequency re-use is foreseen. 2) A wider Tx pulse shape has only been investigated on link level. System level simulations are needed to investigate the impact of a wider pulse shape. Adaptive pulse shaping using pulse shapes within the spectrum mask may give further gains whilst minimising the impact to other users. 3) If a wider pulse shape is to be deployed it is not expected to be used at the edge of an operator's frequency band.	Expected to be fulfilled. 1) No impact on frequency planning or frequency re-use is foreseen. 2) A wider Tx pulse shape has only been investigated on link level and system level. Impacts on legacy MS reception for wider TX pulse shape need to be further investigated. 3) If a wider pulse shape is to be deployed it is not expected to be used at the edge of an operator's frequency band.	Expected to be Fulfilled. 1) No impact on frequency planning or frequency re-use is foreseen. 2) A wide pulse shape has only been investigated on link level. System level simulations are needed to investigate the impact of a wider pulse. 3) If a wide pulse shape is to be deployed it is not expected to be used at the edge of an operator's frequency band.	Expected to be Fulfilled. 1) No impact on frequency planning or frequency re-use is foreseen. 2) A wide pulse shape has not been investigated. 3) If a wide pulse shape is to be deployed it is not expected to be used at the edge of an operator's frequency band.

Classification	Not Fulfilled	Unclear/FFS	Expected to be fulfilled.	Fulfilled

13 Conclusions

During the MUROS feasibility study, opened at GERAN#36, a number of candidate techniques have been investigated that are aimed at increasing voice capacity of GERAN in the CS domain in order of a factor of two per BTS transceiver by creating new types of speech traffic channels in GERAN. These candidate techniques included into this Technical Report are described in chapter 6 to 9, namely

- Speech capacity enhancement using DARP (chapter 6).
- Orthogonal Sub Channels (chapter 7).
- Adaptive Symbol Constellation (chapter 8).
- Higher Order Modulations for MUROS (chapter 9).

The four above listed candidate techniques were evaluated against the defined performance and compatibility objectives defined in chapter 4. The evaluation against performance objectives is reflected in chapter 12 in Table 12-1 and against compatibility objectives in chapter 12 in Table 12-2. .

To summarize this evaluation it was seen that the second and the third candidate technique fulfill the performance and compatibility objectives best, whilst the first three candidate techniques have major conceptual commonalities.

Among these three candidate techniques the Adaptive Symbol Constellation concept has been identified to include techniques common to the co-TCH and the Orthogonal Sub Channels proposals. The solution for the uplink is identical for these three concepts. Voice capacity is increased by multiplexing two users simultaneously on the same radio resource defined by a single time slot, specific ARFCN and specific sequence of TDMA frame numbers as defined for full rate and half rate GSM speech channels.

It is the intention to leave this feasibility study open in order to further investigate enhancements for Rel-9 and beyond. In this context the Higher Order Modulation proposal will be futher studied.
