# ETSI TS 103 634 V1.7.1 (2026-07)

TECHNICAL SPECIFICATION

## Digital Enhanced Cordless Telecommunications (DECT); Low Complexity Communication Codec plus (LC3plus)

Reference
RTS/DECT-00437

Keywords
audio, codec, DECT, full-band, LC3plus, lossless, superwideband, voice, VoIP

***Important notice***

The present document can be downloaded from the ETSI Search & Browse Standards application.

The present document may be made available in electronic versions and/or in print. The content of any electronic and/or print versions of the present document shall not be modified without the prior written authorization of ETSI. In case of any existing or perceived difference in contents between such versions and/or in print, the prevailing version of an ETSI deliverable is the one made publicly available in PDF format on ETSI deliver repository.

Users should be aware that the present document may be revised or have its status changed, this information is available in the Milestones listing.

If you find errors in the present document, please send your comments to the relevant service listed under Committee Support Staff.

If you find a security vulnerability in the present document, please report it through our Coordinated Vulnerability Disclosure (CVD) program.

***Notice of disclaimer & limitation of liability***

The information provided in the present deliverable is directed solely to professionals who have the appropriate degree of experience to understand and interpret its content in accordance with generally accepted engineering or other professional standard and applicable regulations.
No recommendation as to products and services or vendors is made or should be implied.
No representation or warranty is made that this deliverable is technically accurate or sufficient or conforms to any law and/or governmental rule and/or regulation and further, no representation or warranty is made of merchantability or fitness for any particular purpose or against infringement of intellectual property rights.
In no event shall ETSI be held liable for loss of profits or any other incidental or consequential damages.

Any software contained in this deliverable is provided "AS IS" with no warranties, express or implied, including but not limited to, the warranties of merchantability, fitness for a particular purpose and non-infringement of intellectual property rights and ETSI shall not be held liable in any event for any damages whatsoever (including, without limitation, damages for loss of profits, business interruption, loss of information, or any other pecuniary loss) arising out of or related to the use of or inability to use the software.

***Copyright Notification***

No part of this document may be reproduced in any form, by any means and in any media, without the prior written authorization of ETSI and except as expressly permitted below.
By way of exception and when the document is a normative deliverable (European Standard (EN), Technical Specification (TS), Group Specification (GS) or ETSI Standard (ES)), ETSI authorizes to reproduce and incorporate into products, services and technical documentation only those extracts (e.g. templates) that are strictly necessary for the technical implementation of the normative deliverable, to ensure compliance with the latter.
Nothing in this notice shall be construed as limiting any mandatory exceptions to copyright provided by applicable law.

Intellectual Property Rights ..... 11
Foreword ..... 11
Modal verbs terminology ..... 11
Executive summary ..... 12
Introduction ..... 12
1 Scope ..... 13
2 References ..... 13
2.1 Normative references ..... 13
2.2 Informative references ..... 14
3 Definition of terms, symbols and abbreviations ..... 15
3.1 Terms ..... 15
3.2 Symbols ..... 16
3.2.1 Mathematical symbols ..... 16
3.2.2 Operator symbols ..... 16
3.3 Abbreviations ..... 17
4 General description ..... 19
4.1 Overview ..... 19
4.2 Transcoding functions ..... 19
4.3 ANSI C-code ..... 21
4.4 Conformance testing ..... 22
4.5 RTP payload format ..... 22
4.6 Performance characterization ..... 22
5 Codec algorithm description ..... 22
5.1 General codec description ..... 22
5.2 General codec parameters ..... 25
5.2.1 Audio channels ..... 25
5.2.2 Sampling rates ..... 25
5.2.3 Bits per sample ..... 25
5.2.4 Frame size and delay ..... 26
5.2.5 Bit budget and bitrate ..... 26
5.2.6 Bandwidth ..... 26
5.3 Encoding process ..... 27
5.3.1 Encoder modules ..... 27
5.3.2 Input signal ..... 27
5.3.3 Input signal scaling ..... 28
5.3.4 Low Delay MDCT analysis ..... 28
5.3.4.1 Overview ..... 28
5.3.4.2 Update time buffer ..... 28
5.3.4.3 Time-frequency transformation ..... 28
5.3.4.4 Energy estimation per band ..... 29
5.3.4a Near Nyquist detector ..... 30
5.3.5 Bandwidth detector ..... 30
5.3.5.1 Algorithm ..... 30
5.3.5.2 Parameters ..... 31
5.3.6 Time Domain Attack Detector ..... 32
5.3.6.1 Overview ..... 32
5.3.6.2 Downsampling and Filtering of Input Signal ..... 32
5.3.6.3 Energy Calculation ..... 32
5.3.6.4 Attack Detection ..... 32
5.3.7 Spectral Noise Shaping ..... 33
5.3.7.1 Overview ..... 33
5.3.7.2 SNS analysis ..... 33

5.3.7.2.1 Overview ..... 33
5.3.7.2.2 Padding ..... 33
5.3.7.2.3 Smoothing ..... 34
5.3.7.2.4 Pre-emphasis ..... 34
5.3.7.2.5 Noise floor ..... 34
5.3.7.2.6 Logarithm ..... 35
5.3.7.2.7 Band Energy Grouping ..... 35
5.3.7.2.8 Mean removal and scaling, attack handling ..... 35
5.3.7.3 SNS quantization ..... 36
5.3.7.3.1 General ..... 36
5.3.7.3.2 Stage 1 ..... 37
5.3.7.3.3 Stage 2 ..... 37
5.3.7.3.4 Multiplexing of SNS VQ Codewords ..... 42
5.3.7.3.5 Synthesis of the Quantized SNS scale factor vector ..... 44
5.3.7.3a Low Rate SNS quantization ..... 44
5.3.7.3a.1 Low Rate SNS VQ General ..... 44
5.3.7.3a.2 Low Rate SNS VQ Stage 1 ..... 45
5.3.7.3a.3 Low Rate SNS-VQ Stage 2 ..... 48
5.3.7.3a.4 Multiplexing of Low Rate SNS VQ Codewords ..... 53
5.3.7.3a.5 Synthesis of the Quantized Low Rate SNS scale factor vector ..... 54
5.3.7.3a.6 Bit Rate adjustment for Low Rate SNS VQ ..... 55
5.3.7.4 SNS scale factors interpolation ..... 55
5.3.7.5 Spectral shaping ..... 56
5.3.8 Bandwidth control ..... 56
5.3.9 Temporal Noise Shaping (TNS) ..... 56
5.3.9.1 Overview ..... 56
5.3.9.2 TNS analysis ..... 57
5.3.9.3 Quantization ..... 58
5.3.9.4 Filtering ..... 59
5.3.10 Long Term Post Filter (LTPF) ..... 59
5.3.10.1 Overview ..... 59
5.3.10.2 Time-domain signals ..... 60
5.3.10.3 Resampling ..... 60
5.3.10.4 High-pass filtering ..... 60
5.3.10.5 Pitch detection algorithm ..... 61
5.3.10.6 LTPF bitstream ..... 62
5.3.10.7 LTPF pitch-lag parameter ..... 62
5.3.10.8 LTPF activation bit ..... 63
5.3.11 Spectral quantization ..... 64
5.3.11.1 Overview ..... 64
5.3.11.2 Bit budget ..... 64
5.3.11.3 First global gain estimation ..... 65
5.3.11.4 Quantization ..... 67
5.3.11.5 Bit consumption ..... 67
5.3.11.6 Truncation ..... 69
5.3.11.7 Global gain adjustment ..... 69
5.3.12 Residual coding ..... 70
5.3.13 Noise level estimation ..... 70
5.3.13.1 Overview ..... 70
5.3.13.2 Relevant spectral lines ..... 71
5.3.13.3 Noise level calculation ..... 71
5.3.14 Bitstream encoding ..... 72
5.3.14.1 Overview ..... 72
5.3.14.2 Initialization ..... 72
5.3.14.3 Side information ..... 72
5.3.14.3.1 General ..... 72
5.3.14.3.2 Definition of write_LTP_data() (Nms = 1,25) ..... 73
5.3.14.3.3 Definition of write_LRSNS_data() (Nms = 1,25) ..... 73
5.3.14.4 Arithmetic encoding ..... 74
5.3.14.4.1 Overview ..... 74
5.3.14.4.2 Pseudo code implementation ..... 75
5.3.14.5 Residual data and finalization ..... 76

5.3.14.6 Functions ... 77
5.3.15 Encoding of Low Frequency Effects (LFE) ... 79
5.4 Decoding process ... 79
5.4.1 Decoder modules ... 79
5.4.2 Bitstream decoding ... 80
5.4.2.1 Overview ... 80
5.4.2.2 Initialization ... 80
5.4.2.3 Side information ... 80
5.4.2.3.1 General ... 80
5.4.2.3.2 Definition of read_LTP_data() (Nms = 1,25) ... 81
5.4.2.4 Special decoder mode indicators ... 82
5.4.2.5 Padding pattern ... 82
5.4.2.6 Bandwidth interpretation ... 83
5.4.2.7 Arithmetic decoding ... 83
5.4.2.8 Residual data and finalization ... 84
5.4.2.9 Functions ... 86
5.4.3 Residual decoding ... 87
5.4.4 Noise filling ... 88
5.4.5 Global gain ... 88
5.4.6 TNS decoder ... 88
5.4.7 SNS decoder ... 89
5.4.7.1 Overview ... 89
5.4.7.2 SNS scale factor decoding ... 89
5.4.7.2.1 SNS VQ decoding ... 89
5.4.7.2.2 Stage 1 SNS VQ decoding ... 90
5.4.7.2.3 Stage 2 SNS VQ decoding ... 90
5.4.7.2.4 Unit energy normalization of the received shape ... 93
5.4.7.2.5 Reconstruction of the Quantized SNS Scalefactors ... 93
5.4.7.2a Low Rate SNS scale factor decoding ... 94
5.4.7.2a.1 Low Rate SNS VQ decoding ... 94
5.4.7.2a.2 Low Rate SNS configuration and Stage 1 SNS VQ decoding ... 94
5.4.7.2a.3 Low Rate Stage 2 SNS VQ decoding ... 95
5.4.7.2a.4 Low Rate unit energy normalization of the received integer shape vector ... 97
5.4.7.2a.5 Reconstruction of the Quantized Low Rate SNS Scalefactors ... 97
5.4.7.3 SNS scale factors interpolation ... 97
5.4.7.4 Spectral Shaping ... 98
5.4.8 Low delay MDCT synthesis ... 98
5.4.9 Long term postfilter ... 98
5.4.9.1 Overview ... 98
5.4.9.2 Transition handling ... 99
5.4.9.3 Remaining of the frame ... 100
5.4.9.4 Adaptive gain for LTPF ... 101
5.4.10 Output signal scaling and rounding ... 103
5.5 Frame structure ... 103
5.6 Error concealment ... 103
5.6.1 General consideration ... 103
5.6.2 PLC trigger ... 104
5.6.3 PLC method selection and method application ... 104
5.6.3.1 Method selection ... 104
5.6.3.2 MDCT frame repetition with sign scrambling ... 107
5.6.3.3 Time domain concealment ... 109
5.6.3.3.1 Overview ... 109
5.6.3.3.2 LPC parameter calculation ... 109
5.6.3.3.3 Construction of the periodic part of the excitation ... 110
5.6.3.3.4 Construction of the random part of the excitation ... 111
5.6.3.3.5 Construction of the total excitation, synthesis and post-processing ... 113
5.6.3.3.6 Time domain alias cancelation ... 113
5.6.3.3.7 Handling of multiple frame losses ... 114
5.6.3.4 Frequency domain concealment (Phase ECU) ... 115
5.6.3.4.1 Phase ECU overview ... 115
5.6.3.4.2 Spectral Shape ... 115
5.6.3.4.3 Transient analysis ... 116

5.6.3.4.4 Fine Spectral analysis ..... 118
5.6.3.4.4a Noise only analysis and modification ..... 118
5.6.3.4.4b Single sinusoid analysis and modification ..... 119
5.6.3.4.5 Frame reconstruction ..... 119
5.6.4 PLC operation related to LTPF ..... 121
5.7 External rate adaptation ..... 121
5.8 High-resolution audio support ..... 121
5.8.1 Overview ..... 121
5.8.2 Changes to the algorithm in high-resolution mode ..... 122
5.8.3 Void ..... 126
5.9 Tables and constants ..... 126
5.9.1 Band tables index ..... 126
5.9.2 Low delay MDCT windows ..... 127
5.9.2.0 Frame size 1,25 ms ..... 127
5.9.2.1 Frame size 2,5 ms ..... 127
5.9.2.2 Frame size 5 ms ..... 127
5.9.2.3 Frame size 7,5 ms ..... 128
5.9.2.4 Frame size 10 ms ..... 128
5.9.3 SNS quantization ..... 128
5.9.4 Temporal noise shaping ..... 130
5.9.5 Long term postfiltering ..... 130
5.9.6 Spectral data ..... 131
5.10 Lossless audio support ..... 131
5.10.1 Introduction ..... 131
5.10.2 Changes to the algorithm in lossless mode ..... 133
5.10.2.1 Encoding process ..... 133
5.10.2.1.1 Input signal (clause 5.3.2) ..... 133
5.10.2.1.2 Input signal scaling (clause 5.3.3) ..... 134
5.10.2.1.3 Low Delay MDCT analysis (clause 5.3.4) ..... 134
5.10.2.1.4 Spectral Noise Shaping (clause 5.3.7) ..... 137
5.10.2.1.5 Bandwidth Control (clause 5.3.8) ..... 137
5.10.2.1.6 Temporal Noise Shaping (clause 5.3.9) ..... 137
5.10.2.1.7 Long Term Post Filter (clause 5.3.10) ..... 139
5.10.2.1.8 Spectral Quantization (clause 5.3.11) ..... 139
5.10.2.1.9 Deterministic curve and MSB/LSB separation ..... 141
5.10.2.1.10 Deterministic curve for 192 kHz sampling rate and 24 bits per sample PCM input ..... 142
5.10.2.1.11 Arithmetic coding (clause 5.3.14.4) ..... 143
5.10.2.1.12 Residual coding (clause 5.3.12) ..... 144
5.10.2.1.13 Noise level estimation (clause 5.3.13) ..... 147
5.10.2.1.14 Bitstream encoding (clause 5.3.14) ..... 147
5.10.2.1.15 Dynamic Switching to High-Resolution mode ..... 148
5.10.2.1.16 Fallback encoder ..... 149
5.10.2.1.17 Bitstream construction ..... 149
5.10.2.2 Decoding process ..... 150
5.10.2.2.1 Bitstream decoding (clause 5.4.2) ..... 150
5.10.2.2.2 Fallback decoder ..... 151
5.10.2.2.3 Deterministic curve and spectral recombination ..... 151
5.10.2.2.4 Arithmetic decoder (clause 5.4.2.7) ..... 152
5.10.2.2.5 Residual decoder (clauses 5.4.2.8 and 5.4.3) ..... 153
5.10.2.2.6 Noise filling (clause 5.4.4) ..... 153
5.10.2.2.7 Application of global gain (clause 5.4.5) ..... 153
5.10.2.2.8 SNS decoder (clause 5.4.7) ..... 153
5.10.2.2.9 TNS decoder (clause 5.4.6) ..... 154
5.10.2.2.10 Low Delay MDCT synthesis (clause 5.4.8) ..... 154
5.10.2.2.11 Long Term Postfilter (clause 5.4.9) ..... 157
5.10.2.2.12 Output scaling ..... 157
5.10.2.3 General ..... 157

6 Source code description ..... 157
6.1 Overview ..... 157
6.2 Contents of the C source code ..... 158
6.3 File formats ..... 158

6.3.1 Sound file (encoder input and decoder output) ..... 158
6.3.2 Switching profile (encoder input) ..... 158
6.3.3 Parameter bitstream file (encoder output and decoder input) ..... 158
6.4 Test vector package ..... 158

7 Conformance ..... 159
7.1 Overview ..... 159
7.2 Test framework ..... 159
7.2.1 Test material ..... 159
7.2.2 Test permutations and codec parameters ..... 160
7.2.3 Modules under test ..... 160
7.2.4 Quality metric calculation ..... 160
7.2.4.1 Root Mean Square ..... 160
7.2.4.2 Delta ODG value ..... 161
7.2.4.3 Maximum Loudness Difference (MLD) ..... 162
7.2.4.4 Thresholds ..... 163
7.2.4a Lossless metric calculation ..... 163
7.2.4a.0 General ..... 163
7.2.4a.1 Delta Compression ..... 163
7.2.4a.2 Delta Percentage of Lossless Samples ..... 163
7.2.4a.3 Thresholds ..... 164
7.2.5 Software and tools ..... 164
7.2.5.1 Gen_rate_profile ..... 164
7.2.5.2 Eid-xor ..... 164
7.2.5.3 flipG192 ..... 164
7.2.5.4 G.192 bitstream format ..... 164
7.2.5.5 Note to platform-dependent conformance ..... 165
7.2.5.6 Reference conformance test script ..... 165
7.2.5.7 Bitstream Analyzer ..... 165
7.3 Conformance tests ..... 165
7.3.1 Test groups ..... 165
7.3.2 Core coder tests ..... 165
7.3.2.1 SQAM test ..... 165
7.3.2.2 Band limitation test ..... 166
7.3.2.3 Low pass test ..... 166
7.3.2.4 Bitrate switching test ..... 166
7.3.2.5 Bandwidth switching test ..... 166
7.3.3 Concealment tests ..... 167
7.3.3.1 Packet loss concealment ..... 167
7.3.3.2 Partial concealment ..... 167
7.3.4 Channel coder ..... 167
7.3.4.1 Channel coder test for correctable frames ..... 167
7.3.4.2 Channel decoder test for non-correctable frames ..... 167
7.3.4.3 Error protection mode switching test ..... 168
7.3.4.4 Combined channel coding test for correctable frames ..... 168
7.3.4.5 Combined channel coding test for non-correctable frames ..... 168
7.3.4.6 Void ..... 168
7.3.5 High-resolution mode test ..... 169
7.3.5.1 Core coder tests ..... 169
7.3.5.2 Concealment tests ..... 169
7.3.5.3 Channel coder ..... 169
7.3.5.4 Precision tests ..... 170
7.3.5.4.1 General ..... 170
7.3.5.4.2 Total Harmonic Distortion plus Noise ..... 170
7.3.5.4.3 Signal to Noise Ratio ..... 170
7.3.6 Low Frequency Effects (LFE) test ..... 171
7.3.7 1,25 ms mode test ..... 171
7.3.8 Lossless mode test ..... 171
7.3.8.1 General ..... 171
7.3.8.2 Stereo Tests ..... 171
7.4 Mapping conformance test, module and quality metric ..... 172
7.4.1 Encoder ..... 172

7.4.2 Decoder ..... 172
7.4.3 Encoder-Decoder (EncDec) ..... 172
7.5 Quality metric thresholds ..... 173
7.5a Lossless metric thresholds ..... 173
7.6 Conformance criteria ..... 173
7.7 Codec tests ..... 174
7.7.1 General LC3plus test ..... 174
7.7.2 Applications ..... 174

**Annex A (normative): Application layer forward error correction ..... 175**

A.1 Channel Coder ..... 175
A.1.1 Overview ..... 175
A.1.2 Bitrate Conversion ..... 176
A.1.3 General Channel Coder Parameters ..... 177
A.1.3.1 EP mode ..... 177
A.1.3.2 Slot Size ..... 177
A.1.3.3 EPMR ..... 177
A.1.3.4 Combined Channel Coding Flag ..... 177
A.1.4 Derived Channel Coder Parameters ..... 177
A.1.4.1 Number of Code Words ..... 177
A.1.4.2 Code Word Lengths ..... 178
A.1.4.3 Hamming Distances ..... 178
A.1.4.4 Number of Partial Concealment Code Words ..... 178
A.1.4.5 Size of Partial Concealment Block ..... 178
A.1.4.6 CRC Hash Sizes ..... 178
A.1.4.7 Data Size ..... 178
A.1.5 Algorithmic Description of the Channel Encoder ..... 179
A.1.5.1 Input/Output ..... 179
A.1.5.2 Data Pre-Processing ..... 179
A.1.5.3 Reed-Solomon Encoding ..... 180
A.1.5.4 Mode Signalling ..... 181
A.1.5.5 Code Word Multiplexing ..... 182
A.1.6 Algorithmic Description of the Channel Decoder ..... 182
A.1.6.1 Input/Output ..... 182
A.1.6.2 Code Word De-Multiplexing ..... 182
A.1.6.3 Mode Detection ..... 182
A.1.6.3.1 Overview ..... 182
A.1.6.3.2 Stage 1 ..... 183
A.1.6.3.3 Stage 2 ..... 183
A.1.6.4 EPMR Estimation when Frame is not decodable ..... 184
A.1.6.5 Error Correction ..... 185
A.1.6.5.1 Overview ..... 185
A.1.6.5.2 Calculation of Error Locator Polynomials ..... 186
A.1.6.5.3 Calculation of Error Positions ..... 187
A.1.6.5.4 Calculation of Error Symbols ..... 188
A.1.6.6 De-Colouration and RS Decoding ..... 188
A.1.6.7 Data Post-Processing ..... 189
A.1.7 Padding bytes ..... 190
A.1.8 Bit error Concealment ..... 191
A.1.8.1 Reorder Bitstream ..... 191
A.1.8.2 Bit error Concealment trigger ..... 191
A.1.8.3 Partial Concealment ..... 192

A.2 Redundancy frames ..... 195
A.2.1 Overview ..... 195
A.2.2 Example configuration ..... 195

**Annex B (normative): RTP payload format for the LC3plus codec ..... 196**

B.1 Introduction ..... 196

B.2 LC3plus RTP payload format ..... 197

B.2.1 Byte order ..... 197
B.2.2 RTP header usage ..... 197
B.2.2.1 General ..... 197
B.2.2.2 Marker bit ..... 198
B.2.2.3 Sequence number ..... 198
B.2.2.4 Time stamp ..... 198
B.2.3 Packetization Considerations ..... 198
B.2.4 Payload Structure ..... 199
B.2.5 Payload header, frame data length request ..... 199
B.2.6 Table of Contents ..... 200
B.2.7 Forming the payload ..... 202
B.2.8 Speech_bad frame data ..... 203
B.2.9 NO_DATA frames data ..... 203
B.2.10 Example of NO_DATA or Speech_bad in payload ..... 203
B.2.11 Payload examples ..... 204
B.2.11.1 General ..... 204
B.2.11.2 Single-Channel Payload Carrying a Single Frame Encoded with WB at 32 kbit/s ..... 204
B.2.11.3 Single-Channel Payload Carrying a Single Frame Encoded with SWB at 64 kbit/s ..... 205
B.2.11.4 Single-Channel Payload Carrying Two Active Frames Encoded with WB at Different Bitrates ..... 206
B.2.11.5 Multi-Channel Payload Carrying One Frame Block for Two Channels ..... 207
B.2.12 Packetization ..... 208

B.3 Payload format parameters ..... 209
B.3.1 General ..... 209
B.3.2 LC3plus media type registration ..... 209
B.3.3 Mapping media type parameters into SDP ..... 211
B.3.4 Offer-answer model considerations ..... 211
B.3.5 SDP examples ..... 213
B.3.5.1 General ..... 213
B.3.5.2 SDP negotiation for WB ..... 213
B.3.5.3 SDP negotiation for SWB ..... 213

B.4 IANA considerations ..... 214

**Annex C (informative): An example FEC control unit ..... 215**

C.1 Overview ..... 215

C.2 Parameters ..... 215
C.2.1 General ..... 215
C.2.2 Setup Parameters ..... 215
C.2.2.1 Minimal and maximal EP mode ..... 215
C.2.2.2 Perceptual quality table ..... 215
C.2.2.3 Initial FER reduction factors ..... 215
C.2.3 Input Parameters ..... 216
C.2.3.1 General ..... 216

# Intellectual Property Rights

## Essential patents

IPRs essential or potentially essential to normative deliverables (European Standard (EN), Technical Specification (TS), Group Specification (GS) or ETSI Standard (ES)) may have been declared to ETSI. The declarations pertaining to these essential IPRs, if any, are publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI IPR online database.

Pursuant to the ETSI Directives including the ETSI IPR Policy, no investigation regarding the essentiality of IPRs, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

## Trademarks

The present document may include trademarks and/or tradenames which are asserted and/or registered by their owners. ETSI claims no ownership of these except for any which are indicated as being the property of ETSI, and conveys no right to use or reproduce any trademark and/or tradename. Mention of those trademarks in the present document does not constitute an endorsement by ETSI of products, services or organizations associated with those trademarks.

**DECT™**, **PLUGTESTS™**, **UMTS™** and the ETSI logo are trademarks of ETSI registered for the benefit of its Members. **3GPP™**, **LTE™** and **5G™** logo are trademarks of ETSI registered for the benefit of its Members and of the 3GPP Organizational Partners. **oneM2M™** logo is a trademark of ETSI registered for the benefit of its Members and of the oneM2M Partners. **GSM**® and the GSM logo are trademarks registered and owned by the GSM Association.

# Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Digital Enhanced Cordless Telecommunications (DECT).

Clause 4 provides an overview of the LC3plus codec, whilst clause 5 provides detailed algorithmic descriptions of the encoder and the decoder.

Clause 6 introduces the bit-exact, fixed point ANSI C source code, which is attached to the present document, that provides a reference implementation of the LC3plus audio codec. The conformance procedure for verifying optimized implementations is available in clause 7.

Annex A provides a description of the Application Layer Forward Error Correction (AL-FEC) function associated with the LC3plus codec.

Annex B provides the payload format description of LC3plus inside the Real-time Transport Protocol (RTP).

Annex C provides an example algorithm which adaptively controls the FEC strength with respect to the error characteristic of the transport channel.

# Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

# Executive summary

The present document is the specification of the Low Complexity Communication Codec plus (LC3plus), a transformation-based audio codec operating at all common sampling rates and a wide range of bit rates. The present document includes beside the technical description of the core codec also packet loss concealment and forward error correction schemes such as a channel coder to be ready for use in applications like VoIP and DECT. Besides voice applications, the codec is also applicable for high quality music transmission up to transparency.

LC3plus additionally supports a lossless coding mode that provides bit-exact reconstruction of the input audio signal on the decoder side and operates at sampling rates up to 192 kHz. The lossless mode features a deterministic upper bound on the encoded bitrate of (bits_per_audio_sample + 1) · $f_s$ through an integrated fallback mechanism, making the codec suitable for applications that require predictable transport bandwidth even under worst-case signal conditions.

# Introduction

With the introduction of the 3GPP Enhanced Voice Services (EVS) [i.1] in 2014, the mobile voice communication was enriched with the SWB audio quality. However, this technical development came along with a significant increase in computational complexity and memory demands which limits the deployment to relatively powerful mobile phones. LC3plus aims to provide the low complexity counterpart of EVS in order to make SWB also available on low-cost terminals such as VoIP or DECT. The codec allows perfect interoperability between mobile and other networks by means of transcoding and fits complexity wise very well to the requirements of DECT and VoIP terminal equipment. Due to the codec's flexible design the applications are not limited to voice services but can be extended to high quality music streaming as well. Running in lossless mode the codec allows bit-exact reconstruction of the encoded signal on the decoder side. If bit rate restrictions apply, the codec dynamically switches to high-resolution mode making maximum use of the available bit budget.

# 1 Scope

The present document contains the specification of the Low Complexity Communication Codec plus (LC3plus). The specification includes a full algorithmic description of both the encoder and the decoder. It includes reference fixed-point and floating-point ANSI C source code and conformance test procedures.

The codec has been designed on the one hand for Digital Enhanced Cordless Telecommunications (DECT) and the New Generation DECT (NG-DECT) systems but also for VoIP and other applications such as music streaming.

The LC3plus codec provides the following basic features:

- Capability for speech and audio coding.
- Several low delay modes.
- Low computational complexity.
- Multiple bitrates from 16 kbit/s up to 320 kbit/s in normal mode, higher in high resolution and in lossless mode.
- Multiple audio bandwidths from narrow band to full-band and ultra-band, additionally 96 kHz audio bandwidth in lossless mode.
- High- resolution mode for high precision, high dynamic range and audio bandwidth up to the Nyquist frequency also for ultra-band.
- Advanced error concealment.
- Lossless mode for bit-exact reconstruction of audio content on decoder side, with automatic and seamless switching to high-resolution mode, including support for 192 kHz sampling frequency / 96 kHz audio bandwidth, and a verbatim fallback path that bounds the maximum bitrate to (bits_per_audio_sample + 1) $f_s$ per channel.
- Application Layer Forward Error Correction (AL-FEC) including channel coder functionality.
- RTP payload format.

# 3 Definition of terms, symbols and abbreviations

## 3.1 Terms

For the purposes of the present document, the following terms apply:

**codec redundancy:** redundancy created by the LC3plus codec

NOTE: The codec encodes two variants of a frame, one primary encoding and one secondary (or redundant) encoding. The primary encoding typically uses more bits than the secondary encoding.

**frame:** portion of the media for a single channel, e.g. speech or audio or a combination thereof, that is input to the encoder or output of the decoder for one channel

NOTE: A frame includes a frame duration of audio (see frame duration definition below).

**frame aggregation:** encapsulation of several non-redundant frames within the same packet

**frame data:** encoded media for a single audio frame and a single channel, either output from the encoder or input to the decoder

NOTE: Frame data may include any of the following: active audio, Silence Description (SID), NO_DATA frame or Speech_bad frame. The frame data is not protected with the channel coding specified in Annex A.

**frame data block:** frame data for one or more channels for a single frame period

NOTE: For mono input audio signals, a frame data block includes the frame data for a single audio frame, see frame data. In this case, the frame data block is identical to the frame data. For stereo and multi-channel input audio signals, a frame data block contains the frame data from all channels. Thereby, a frame data block includes the same number of frames as there are channels.

**frame duration:** time duration for a frame

NOTE: The frame duration is either 1,25 ms (excluding NB), 2,5 ms, 5 ms, 7,5 ms or 10 ms. For FBCD, the frame duration is either approximately 1,36 ms, 2,72 ms, 5,44 ms, 8,16 ms or approximately 10,88 ms.

**frame period:** time period for a frame, from time T until time T+frame_duration

**full-band:** speech or audio sampled at 48 kHz

**full-band, compact disc:** speech or audio sampled at 44,1 kHz

**high-resolution mode:** LC3plus operation mode for higher bit rates, higher precision and wider audio bandwidth

**lossless mode:** LC3plus operation mode for bit-exact reconstruction of encoded audio input signal on decoder side.

NOTE: If bitrate restrictions do not allow lossless encoding, the codec seamlessly switches to high resolution mode to guarantee the best THD+N and SNR performance for the given bitrate at any time.

**narrow-band:** speech or audio sampled at 8 kHz

**NO_DATA frame:** type of frame data that spends no bits on encoding the audio

NOTE: A NO_DATA frame is sometimes included when creating the payload and a frame needs to be included but no active frame or SID frame is available, for example when sending redundancy with offset or multi-channel audio where some channels are idle or in DTX.

**no request (NO_REQ):** type of FDLR that includes no adaptation request

**semi-super-wideband:** speech or audio sampled at 24 kHz

**speech_bad frame:** type of frame data indicating that the frame data has been discarded because of errors

NOTE: For example, when a media gateway detects bit errors in the frame data it may discard the frame data and instead send a Speech_bad frame towards the receiver to explicitly indicate that the frame data was dropped.

**super-wideband:** speech or audio sampled at 32 kHz

**ultra-band:** speech or audio sampled at 96 kHz

**wideband:** speech or audio sampled at 16 kHz

# 3.2 Symbols

## 3.2.1 Mathematical symbols

For the purposes of the present document, the following mathematical symbols apply:

| | |
|---|---|
| $\Delta_{ODG}$ | Difference between two ODG values |
| $D$ | Algorithmic delay of the codec |
| $D_{frame}$ | Delay due to the frame size |
| $D_{MDCT}$ | Delay due to the MDCT look ahead |
| $E_B(b)$ | Energy per band |
| $f_s$ | Sampling rate |
| $I_{f_s}(n)$ | Band indices in dependency of sampling rate |
| $nbytes$ | Number of bytes (octets) per frame |
| $nbits$ | Number of bits per frame ($8 \cdot nbytes$) |
| $N_b$ | Number of bands, i.e. number of entries in $I_{f_s} - 1$ |
| $N_C$ | Number of audio channels |
| $N_{bw}$ | Number of bandwidth sections |
| $N_E$ | Number of encoded spectral lines |
| $N_F$ | Number of samples processed in one frame a.k.a frame size |
| $N_{ms}$ | Frame duration specified in milliseconds |
| $w_N$ | Low Delay MDCT window |
| $X(k)$ | Frequency Coefficients |
| $x_b(n)$ | Time domain sample of block b and index n |
| $X_b(k)$ | Frequency domain bin of block b and frequency index k |
| $Z$ | Number of leading zeros in MDCT window |

## 3.2.2 Operator symbols

For the purposes of the present document, the following operator symbols apply:

| | |
|---|---|
| *a mod b* | Modulo operator defined by $a - b \left\lfloor \frac{a}{b} \right\rfloor$ |
| {*x*\|*condition(x)*} | Defines the quantity of *x* where *x* fulfils a certain condition |
| $x^T$, $X^T$ | The transpose of vector *x* and matrix *X* respectively |
| *a* \| *b* | Set construction operator with elements *a* such that *b* is fulfilled |
| *argmax X* | Returns the position of the first occurrence of the maximum value of array *X* |
| *argmin X* | Returns the position of the first occurrence of the minimum value of array *X* |
| $nint(x)$ or $\lfloor x \rceil$ | Round *x* to nearest integer, e.g. $\lfloor 3{,}2 \rceil = 3;\ \lfloor 4{,}5 \rceil = 5$ |
| $\lfloor x \rfloor$ | Round *x* to next lower integer, e.g. $\lfloor 3{,}2 \rfloor = 3;\ \lfloor 4{,}5 \rfloor = 4$ |
| $\lceil x \rceil$ | Round *x* to next higher integer, e.g. $\lceil 3{,}2 \rceil = 4;\ \lceil 4{,}5 \rceil = 5$ |
| $\{a, b, ..\}$ | Ordered sequence of values. Indexing starts with 0, if not specified otherwise |
| $a(n..m)$ | Sequence of values indexed from $n$ to $m$, i.e. $\{a(n), a(n+1), \dots, a(m)\}$ |
| $x \leftarrow y$ | Reading from $y$ and storing in $x$. Defines in-place operations with formulas, e.g. $x(n) \leftarrow x(n+1)$ shifts samples in $x$ by one |
| & | bitwise AND operation |
| \| | bitwise AND operation |
| ^ | bitwise XOR operation |

| | |
|---|---|
| >> | bitwise shift towards right |
| << | bitwise shift towards left |
| · | multiplication |

NOTE: For compatibility reasons the dot multiplication symbol has been retained exceptionally in the present document over the multiplication symbol usually used in all ETSI deliverables.

## 3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

| | |
|---|---|
| AL-FEC | Application Layer FEC |
| ALU | Arithmetic Logic Unit |
| ANSI-C | American National Standards Institute C |
| ATH | Absolute Threshold for Hearing curve |
| BEC | Bit Error Condition |
| BFI | Bad Frame Indicator |
| BW | BandWidth |
| BWR | BandWidth and Resolution (index) |
| CBR | Constrained Bit Rate |
| CC | Channel Counter |
| CD | Compact Disc |
| CR | Change Request |
| CRC | Cyclic Redundancy Check |
| DC | Direct Current |
| DCT | Discrete Cosine Transform |
| DCT-II | Discrete Cosine Transform type II |

# 4 General description

## 4.1 Overview

The LC3plus codec can operate at highly flexible modes. For regular operation mode, the codec supports coding of speech and audio for several audio bandwidths, using the sampling frequencies 8 kHz, 16 kHz, 24 kHz, 32 kHz or 48 kHz. The LC3plus codec may also be used for streaming audio and therefore also supports CD sampling rate (44,1 kHz). It supports encoding and decoding using either a 1,25 ms, 2,5 ms, 5 ms, 7,5 ms or 10 ms frame duration. A large number of compressed frame sizes from 20 bytes to 400 bytes can be configured, see also the feature summary in Table 5.1. Note, that the 7,5 ms frame duration is supported for other wireless systems besides DECT.

To support different use cases and varying operation conditions, the LC3plus includes support for end-to-end adaptation of both the coded audio bandwidth and the bitrate.

The LC3plus also includes a high-resolution coding mode using Full-Band (FB) and Ultra-Band (UB) audio encoding at sampling frequencies of 48 kHz and 96 kHz with maximum frame sizes of 625 bytes for a 10 ms frame duration. Frame durations of 1,25 ms, 2,5 ms, 5 ms and 7,5 ms are supported as well. The high-resolution mode targets higher bit-rates, higher Signal-To-Noise ratios and coding the full audio spectrum up to the Nyquist frequency. The supported configurations are listed in Table 5.2.

In its lossless mode, LC3plus allows bit-exact reconstruction of the encoded signal on decoder side if allowed by a given bitrate constraint. In case the bit budget defined by the bitrate parameter is not sufficient for lossless encoding, LC3plus automatically and seamlessly switches to high-resolution encoding making optimal use of the available bit budget, thus at any time providing the highest possible quality for any given bitrate. Additionally, 192 kHz audio sampling rate is supported in lossless mode.

The LC3plus codec provides a flexible error concealment algorithm, optimized both for all kind of audio signals. LC3plus is further associated with Application Layer Forward Error Correction (AL-FEC) including a channel coder functionality, which is essential if bit errors in the transport layer are propagated up to the application layer. It supports the usage of redundancy packets as AL-FEC strategy for packet-based networks.

An RTP payload format is available in Annex B for transmission over IP/UDP for e.g. VoIP applications.

## 4.2 Transcoding functions

This clause provides a high-level overview of the operation of the LC3plus including the interfaces and configuration options. Figures 4.1, 4.2 and 4.3 outline possible LC3plus configuration scenarios. The full technical details of the codec are provided in clause 5 of the present document.

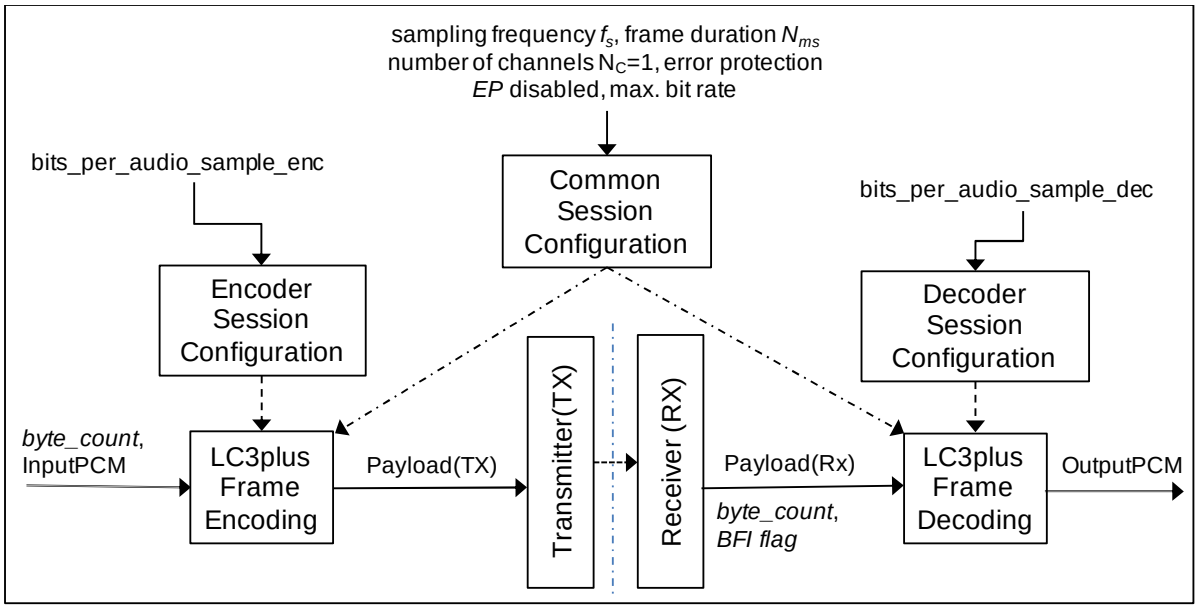

**Figure 4.1: LC3plus operation for one channel without error protection**

As shown in Figure 4.1, a LC3plus encoder takes PCM input samples and creates compressed frames which are transmitted to the receiver side where the frames are decoded and the PCM data is restored. Configuration parameters which usually need to be identical at encoder and decoder side are sampling rate, frame duration, error protection enabled/disabled flag. Those parameters usually do not change during a session.

The bits per audio sample may differ at encoder and decoder side, as those values are independent from the transmitted LC3plus frame. The encoder may compress a 24 bits per sample PCM input and the decoder may render it with 16 bits per sample and vice versa.

The decoder requires the length information for the LC3plus frame (*byte_count*) in order to apply decoding. In addition, the decoder accepts Bad Frame Indicators (*BFI_flag*). If *BFI_flag* unequal zero, the LC3plus frame is considered as missing, partially corrupt or as a redundancy frame at lower quality. In that case the LC3plus decoder applies concealment. For a zero *BFI_flag*, the decoder applies the regular process for rendering the frame to PCM data.

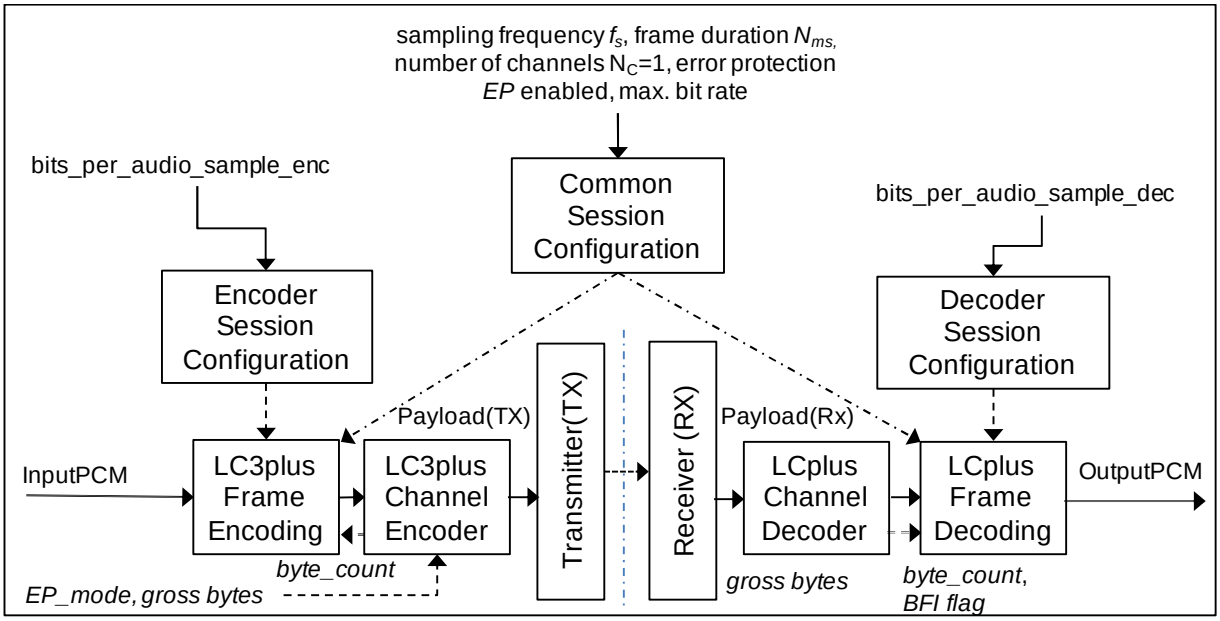

**Figure 4.2: LC3plus operation for one channel including channel coder for error protection**

Figure 4.2 outlines the LC3plus operation with enabled error protection where the channel coder is creating protected payloads.

The channel encoder is initialized with the number of *gross bytes* (channel coding bytes plus source coding bytes) and the *EP_mode* for selecting the strength of the error protection capability. The *EP_mode* can be changed on a frame by frame basis. For error protected payloads, the gross rate is usually kept constant for all EP modes. Increasing protection capability comes along with decreased bit rate for the codec. The channel coder requests a LC3plus frame with a certain codec rate (*byte_count*) depending on *gross bytes* and *EP_mode.*

The LC3plus channel decoder is able to detect the applied EP mode for a given gross rate and payload. It extracts the potentially corrected LC3plus frame and the related frame sizes (*byte_count*). The tool provides further information on the channel characteristic, e.g. the number of distorted bits. The channel decoder controls the *BFI_flag* signalling whether the payload is correct, partially correct or not reliable.

The channel coder also transports Error Protection Mode Requests (EPMRs), a two-bit field indicating which EP mode should be used for encoding at the other side in bi-directional setups.

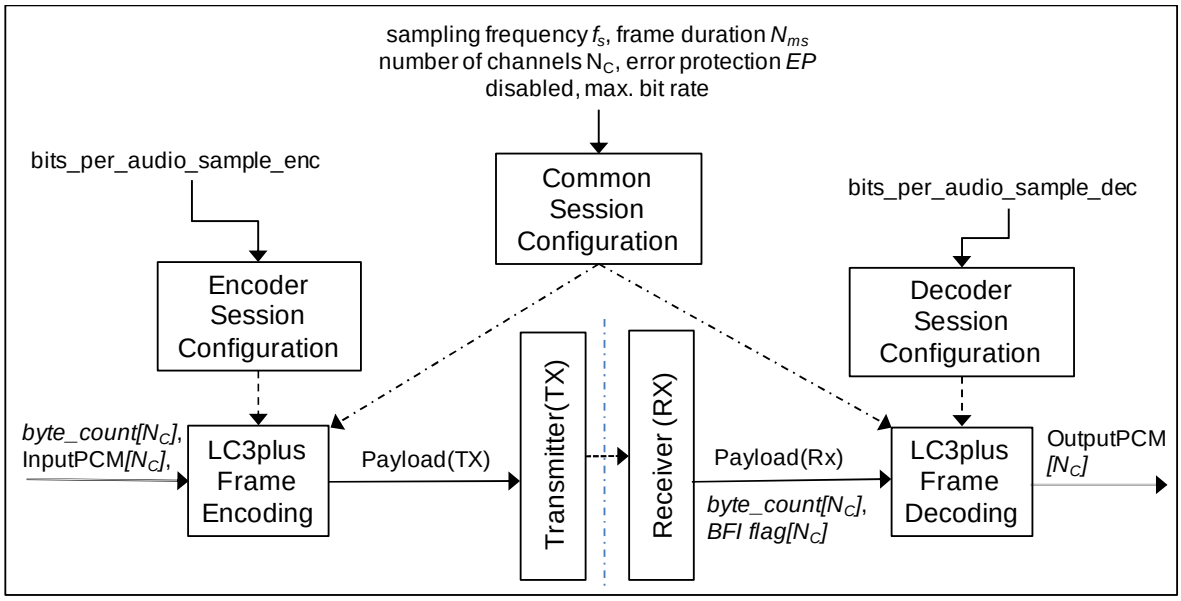

**Figure 4.3: LC3plus operation for multiple audio channels**

Figure 4.3 outlines LC3plus operating for coding multiple audio channels. The number of audio channels $N_C$ are usually the same on encoder and decoder side, however may be switched during the session due to bit rate constraints. Multiple audio channels are compressed as independent single channels which requires an appropriate payload format for transmission.

The encoder compresses $N_C$ PCM input buffers representing different audio channels. Each LC3plus frame may be compressed using a different bit rate (*byte_count*) which may change on frame by frame basis over time for each channel.

## 4.3 ANSI C-code

A reference ANSI C-code implementation of the LC3plus codec is available in archive ts_103634v010701p0.zip which accompanies the present document, see clause 6 for a more detailed description. The ANSI C-code implementation is available in fixed-point arithmetic for efficient implementation in fixed-point Digital Signal Processors (DSPs). Additionally, a version for floating-point arithmetic is provided. Any feature limitation of the two versions is listed in the Readme contained in archive ts_103634v010701p0.zip which accompanies the present document.

In case of differences between the description in the present document and the ANSI C-code, the ANSI C-code shall be used.

The C-code package contains a set of test vectors available in archive ts_103634v010701p0.zip which accompanies the present document, to verify that the compilation of the fixed-point reference implementation and of the floating-point reference implementation operates as expected, see clause 6.4.

## 4.4 Conformance testing

Conformance tests are defined in clause 7, testing encoder, decoder and complete codec implementations of any kind of arithmetic, precision and platform. For that, the implementation under test is compared against the fix-point reference executable and the difference is evaluated using quality metrics such as Root Mean Square, Maximum Loudness Difference or Objective Difference Grade. The compilation of the fix-point reference executable and the floating-point reference executable shall be done without any source code modifications and the resulting reference executables shall be verified with the provided test vector package, see clause 6.4.

The conformance for the high-resolution mode is based on a comparison to the floating-point reference executable and includes besides quality tests also metrics measuring the precision of the implementation under test. The conformance procedure is specified in clause 7.3.5.

All other conformance tests except for the high-resolution mode conformance shall use the fixed-point executable as reference.

## 4.5 RTP payload format

An RTP payload format for transporting LC3plus encoded audio in IP/UDP/RTP is defined in Annex B. The RTP payload format supports all possible combinations of frame durations, audio bandwidths and bitrates the LC3plus codec may generate.

The RTP payload format also defines configuration parameters that can be used to negotiate how the LC3plus codec can be used in a particular session, for example when the Session Description Protocol (SDP), IETF RFC 8866 [4], is used.

## 4.6 Performance characterization

The LC3plus characterization is available in ETSI TR 103 633 [i.5].

# 5 Codec algorithm description

## 5.1 General codec description

This clause describes the technical details of the Low Complexity Communication Codec plus (LC3plus). The main features of LC3plus coding one audio channel are:

**Table 5.1: Feature summary**

| Feature | Supported Range |
|---|---|
| Frame duration | 1,25 ms, 2,5 ms, 5 ms, 7,5 ms and 10 ms (1,36 ms, 2,72 ms, 5,44 ms, 8,16 ms and 10,88 ms @ 44,1 kHz) |
| Look ahead delay | • 1,25 ms (1,36 @ 44,1 kHz) for frame duration of 1,25 ms<br>• 2,5 ms (2,72 ms @ 44,1 kHz) for frame durations of 2,5 ms, 5 ms and 10 ms<br>• 4 ms (5,017 ms @ 44,1 kHz) for frame duration of 7,5 ms |
| Total algorithmic delay | Frame duration + Look ahead delay = 5 ms, 7,5 ms, 11,5 ms and 12,5 ms (for sampling rates other than 44,1 kHz), 2,5 ms for frame duration of 1,25 ms |
| Supported sampling rates | 8 (except for frame duration of 1,25 ms), 16, 24, 32, 44,1 and 48 kHz |
| Audio bandwidth | Maximum 20 kHz for 48 kHz |

| Feature | Supported Range |
|---|---|
| Supported Bit rate | Depends on frame duration and sampling rate:<br>• 20 to 143 bytes per frame and channel for 10 ms and 8 kHz<br>• 20 to 277 bytes per frame and channel for 10 ms and 16 kHz<br>• 20 to 393 bytes per frame and channel for 10 ms and 24 kHz<br>• 20 to 400 bytes per frame and channel for 10 ms and 32 kHz<br>• 20 to 400 bytes per frame and channel for 10 ms and 48 kHz<br>• 20 to 143 bytes per frame and channel for 7,5 ms and 8 kHz<br>• 20 to 277 bytes per frame and channel for 7,5 ms and 16 kHz<br>• 20 to 393 bytes per frame and channel for 7,5 ms and 24 kHz<br>• 20 to 400 bytes per frame and channel for 7,5 ms and 32 kHz<br>• 20 to 400 bytes per frame and channel for 7,5 ms and 48 kHz<br>• 20 to 163 bytes per frame and channel for 5 ms and 8 kHz<br>• 20 to 200 bytes per frame and channel for 5 ms and not 8 kHz<br>• 20 to 100 bytes per frame and channel for 2,5 ms<br>• 20 to 80 bytes per frame and channel for 1,25 ms and not 8 kHz<br><br>If channel coder is active the supported gross bitrates start from 40 bytes up to highest supported codec rate<br><br>LC3plus decoder shall accept up to 400 bytes per frame independent of frame duration |
| Supported bits per audio sample | No restriction by the algorithm, however optimized for 16, 24, 32 bit depth input, see the limitation described in clause 5.2.3 |

The LC3plus furthermore features a high-resolution mode for sampling frequencies of 48 kHz and 96 kHz. The main features of this mode are:

**Table 5.2: Feature Summary High-Resolution Mode**

| Feature | Supported Range |
|---|---|
| Frame duration | 1,25 ms, 2,5 ms, 5 ms, 7,5 ms and 10 ms |
| Look ahead delay | 1,25 ms (1,36 @ 44,1 kHz) for frame duration of 1,25 ms,<br>2,5 ms (2,72 ms @ 44,1 kHz) for frame durations of 2,5 ms, 5 ms and 10 ms<br>4 ms (5,017 ms @ 44,1 kHz) for frame duration of 7,5 ms |
| Total algorithmic delay | Frame duration + Look ahead delay = 2,5 ms, 5 ms, 7,5 ms, 11,5 ms, and 12,5 ms |
| Supported sampling rates | 48 kHz and 96 kHz |
| Audio bandwidth | Always up to the Nyquist frequency |

| Feature | Supported Range |
|---|---|
| Supported Bit rate (per frame and channel) | The following rates are recommended for regular channel operation depending on sampling frequency and frame duration:<br>• 156 to 625 bytes per frame at 48 kHz, 10 ms<br>• 187 to 625 bytes per frame at 96 kHz, 10 ms<br>• 117 to 475 bytes per frame at 48 kHz, 7,5 ms<br>• 141 to 475 bytes per frame at 96 kHz, 7,5 ms<br>• 93 to 375 bytes per frame at 48 kHz, 5 ms<br>• 109 to 375 bytes per frame at 96 kHz, 5 ms<br>• 54 to 210 bytes per frame at 48 kHz, 2,5 ms<br>• 62 to 210 bytes per frame at 96 kHz, 2,5 ms<br>• 32 to 122 bytes per frame at 48 kHz, 1,25 ms<br>• 36 to 122 bytes per frame at 96 kHz, 1,25 ms<br><br>For fallback operation under challenging channel conditions, the minimum bytes per frame ($nbytes_{min}$) might be reduced to $nbytes'_{min} = \left\lfloor \frac{nbytes_{min}}{2} \right\rfloor$.<br><br>If channel coder is active the supported bitrates corresponds to:<br>• 140 to 400 bytes per frame at 48 kHz, 10 ms<br>• 164 to 400 bytes per frame at 96 kHz, 10 ms<br>• 110 to 400 bytes per frame at 48 kHz, 7,5 ms<br>• 126 to 400 bytes per frame at 96 kHz, 7,5 ms<br>• 87 to 375 bytes per frame at 48 kHz, 5 ms<br>• 101 to 375 bytes per frame at 96 kHz, 5 ms<br>• 54 to 210 bytes per frame at 48 kHz, 2,5 ms<br>• 61 to 210 bytes per frame at 96 kHz, 2,5 ms<br>• 32 to 122 bytes per frame at 48 kHz, 1,25 ms<br>• 36 to 122 bytes per frame at 96 kHz, 1,25 ms<br><br>LC3plus decoder shall accept payloads down to 20 bytes per frame independent of frame duration |
| Supported bits per audio sample | No restriction by the algorithm, however optimized for 24, 32 bit depth input, see the limitation described in clause 5.2.3 |

The high-resolution mode is not compatible with the other modes of LC3plus. The support and usage of the high-resolution mode shall be negotiated out of band. The high-resolution extension is described separately in clause 5.8 as a differential description to clauses 5.2 to 5.7.

Additionally, LC3plus offers a lossless mode for sampling frequencies of 44,1 kHz, 48 kHz, 96 kHz and 192 kHz. The main features of this mode are shown in table 5.2a.

**Table 5.2a: Feature Summary Lossless Mode**

| Feature | Supported Range |
|---|---|
| Frame duration | 1,25 ms, 2,5 ms, 5 ms, 7,5 ms and 10 ms |
| Look ahead delay | 1,25 ms for frame duration of 1,25 ms<br>2,5 ms (2,72 ms @ 44,1 kHz) for frame durations of 2,5 ms, 5 ms and 10 ms<br>4 ms (5,017 ms @ 44,1 kHz) for frame duration of 7,5 ms |
| Total algorithmic delay | Frame duration + Look ahead delay = 2,5 ms, 5 ms, 7,5 ms, 11,5 ms, and 12,5 ms |
| Supported sampling rates | 44,1 kHz, 48 kHz, 96 kHz and 192 kHz |
| Audio bandwidth | Always up to the Nyquist frequency |
| Supported Bit rate (per frame and channel) | The minimum bitrate for lossless coding is equal to the fallback rate for high-resolution coding as defined in Table 5.2.<br>The maximum bitrate for lossless coding is calculated as $maxBR = (bits_per_audio_sample + 1) \cdot N_F$ |
| Supported bits per audio sample | 16 and 24 |

NOTE: The maximum bitrate above is enforced by the WTDA verbatim fallback path (clause 5.10.2.1.16). Expressed in kbit/s per channel, it evaluates to:

- 44,1/48 kHz 16-bit: 816 kbit/s
- 44,1/48 kHz 24-bit: 1 200 kbit/s
- 96 kHz 16-bit: 1 632 kbit/s
- 96 kHz 24-bit: 2 400 kbit/s
- 192 kHz 16-bit: 3 264 kbit/s
- 192 kHz 24-bit: 4 800 kbit/s

The lossless mode is not compatible with the other modes of LC3plus. The support and usage of the lossless mode as well as the used bits per sample shall be negotiated out of band. The lossless extension is described separately in clause 5.10 as a differential description to clauses 5.2 to 5.7 and 5.8.2.

The description uses both floating point and integer data format representations, assuming that implementations on platforms with 16, 24, 32 and 64-bit word length using fixed or floating point ALU can be realized with adequate precision.

For all read and write operations, the little-endian bit ordering shall be used.

# 5.2 General codec parameters

## 5.2.1 Audio channels

The algorithm describes only the coding of a single audio channel. Any stereo or multi-channel coding shall be supported by coding of multiple mono streams.

## 5.2.2 Sampling rates

The codec supports the sampling rates $f_s$ of 8 000 Hz, 16 000 Hz, 24 000 Hz, 32 000 Hz, 44 100 Hz and 48 000 Hz. For the 44 100 Hz mode, all configurations, e.g. frame size in number of samples, are identical to the 48 000 Hz mode.

A sampling rate index is defined as follows:

$$f_s^{ind} = \min\left(4, \frac{f_s}{8\,000} - 1\right) \quad (1)$$

The sampling rate index for the relevant sampling frequencies are given in Table 5.3.

**Table 5.3: Sampling rate index function**

| $f_s$ (Hz) | 8 000 | 16 000 | 24 000 | 32 000 | 44 100/48 000 |
|---|---|---|---|---|---|
| $f_s^{ind}$ | 0 | 1 | 2 | 3 | 4 |

## 5.2.3 Bits per sample

The codec algorithm itself has the restriction that the sample resolution is limited to a maximum of 32 bits per audio sample of the input and output audio samples. Typical values are 16, 24 or 32 bits per audio sample.

### 5.2.4 Frame size and delay

The codec works at a frame duration $N_{ms}$ of 1,25 ms, 2,5 ms, 5 ms, 7,5 ms and 10 ms resulting in a frame length $N_F = \frac{f_s \cdot f_{scal} \cdot N_{ms}}{1\,000}$ samples, where:

$$f_{scal} = \begin{cases} \frac{48\,000}{44\,100}, for\ f_s = 44\,100\ Hz \\ 1\quad, otherwise \end{cases} \tag{2}$$

The algorithmic delay of the codec $D$ consists of the delay due to frame length $D_{frame}$ and the overlap of the MDCT $D_{MDCT}$. The delays in samples are given by $D_{frame} = N_F$, $D_{MDCT} = N_F - 2Z$ where $Z$ is the number of leading zeros in the MDCT window. The MDCT overlap towards future samples in milliseconds is given by $Z_{ms}$ as outlined in Table 5.4. $Z$ is therefore given by $Z = \frac{N_F}{2} - Z_{ms} \cdot \frac{f_s \cdot f_{scal}}{1\,000}$. The algorithmic delay of the codec is determined by $D = D_{frame} + D_{MDCT}$. Table 5.4 outlines typical delay value.

**Table 5.4: Algorithmic codec delay $D$ depending on frame size $N_{ms}$ and sampling rate $f_s$**

| $N_{ms}$ | $Z_{ms}$ | $f_s \in [8\,000, 16\,000, 24\,000, 32\,000, 48\,000]$ | $f_s \in [44\,100]$ |
|---|---|---|---|
| **1,25 ms** | 0,625 ms | 2,5 ms | 2,72 ms |
| **2,5 ms** | 1,25 ms | 5 ms | 5,44 ms |
| **5 ms** | 1,25 ms | 7,5 ms | 8,16 ms |
| **7,5 ms** | 2 ms | 11,5 ms | 12,517 ms |
| **10 ms** | 1,25 ms | 12,5 ms | 13,6 ms |

### 5.2.5 Bit budget and bitrate

The number of bytes available in one frame is denoted $nbytes$. The number of bytes $nbytes$ to use for encoding a single channel is a required external input to each single channel LC3plus encoder. The same number of bytes (now to be used for decoding) is also a required external input to each single channel LC3plus decoder. The corresponding number of bits available in one frame is thus $nbits = 8 \cdot nbytes$. And the bitrate of the codec in kilobits per second (kbit/s) is then $bitrate = \frac{nbits}{frame_duration} = \frac{nbits}{N_{ms}} = \frac{8 \cdot nbytes}{N_{ms}}$.

The algorithm is verified for the bit rate range from $nbytes = 20$ up to $nbytes = 400$ per channel for all sampling rates.

**Table 5.5: Examples for bit rates depending on bytes per frame ($nbytes$) and frame duration ($N_{ms}$)**

| $N_{ms}$ | $nbytes$ | | | | | |
|---|---|---|---|---|---|---|
| | **20** | **40** | **80** | **120** | **160** | **400** |
| **1,25 ms** | 128 kbps | 256 kbps | 512 kbps | 768 kbps | 1 024 kbps | 2 560 kbps |
| **2,5 ms** | 64 kbps | 128 kbps | 256 kbps | 384 kbps | 512 kbps | 1 280 kbps |
| **5 ms** | 32 kbps | 64 kbps | 128 kbps | 192 kbps | 256 kbps | 640 kbps |
| **7,5 ms** | 21,33 kbps | 42,66 kbps | 85,33 kbps | 128 kbps | 170,66 kbps | 426,66 kbps |
| **10 ms** | 16 kbps | 32 kbps | 64 kbps | 96 kbps | 128 kbps | 320 kbps |

The present document does not specify nor recommend what bitrate to use for encoding a frame of audio samples, this will be specified by the application making use of the LC3plus codec.

### 5.2.6 Bandwidth

The parameter $B$ represents the audio bandwidth in Hz and is by default $B = \min\left(\frac{f_s}{2}, 20\,000\right) \cdot f_{scal} \cdot B$ may be set externally to a lower value, which will limit the spectrum (clause 5.3.8) and deactivate the bandwidth detector (clause 5.3.5). The external value shall represent the supported audio bandwidths NB, WB, SSWB, SWB and FB, i.e. 4 000 Hz, 8 000 Hz, 12 000 Hz, 16 000 Hz, or 20 000 Hz.

To increase audio quality for low bitrates, $B$ shall be limited to a corrected bandwidth $B_c$ of 12 000 Hz as follows:

$$B_c = \begin{cases} \min(12\,000, B), if\ ((f_s = 32\,000\ and\ nbytes < 36)\ or \\ (f_s = 48\,000\ and\ nbytes < 40))\ and\ N_{ms} = 10 \\ B, else \end{cases} \quad (2.1)$$

where $nbytes$ describes the bytes per frame and channel, $f_s$ the sampling frequency and $N_{ms}$ the frame duration. For combined channel coding $nbytes$ is the minimum of both channels.

For encoding Low Frequency Effects (LFE) channels, the encoder should follow the procedure in clause 5.3.15.

# 5.3 Encoding process

## 5.3.1 Encoder modules

A high-level overview of the encoding modules is given in Figure 5.1. The coder is a spectral transform coder which converts a segment of the time domain into a spectral representation (using a LD-MDCT transform). The corresponding frequency components are processed by a Spectral Noise Shaping (SNS) module to reduce perceived spectral quantization noise. The SNS-module contains a vector quantizer, where the first stage is a split VQ and the second stage is a low complexity algorithmic Pyramid VQ. Subsequently, a Temporal Noise Shaping (TNS) module is used to reduce perceived temporal quantization noise. The SNS and TNS shaped components are quantized by a spectral quantizer module. For the spectral coefficients that are quantized to 0, the decoder will substitute these zero values by noise to reduce artifacts. The Noise Level module computes the proper level to be used by the decoder. Eventually the spectral coefficients are entropy encoded and multiplexed into the bitstream. Two additional modules are included in the encoder. A BW detector module is used to determine if the signal is oversampled and contains high frequency spectral coefficients without energy. This information is shared with the TNS and Noise Level estimator to restrict their usage to the active signal region. The decoder uses a pitch based postfilter (LTPF), and the associated pitch is determined in the encoder and transmitted to the decoder.

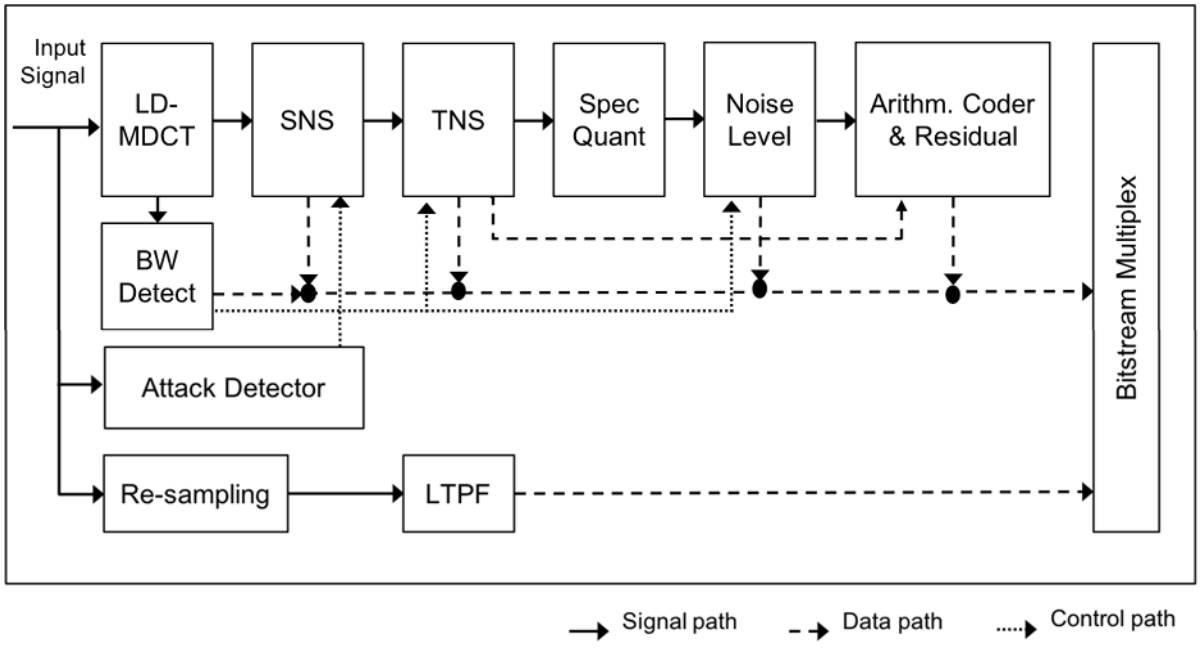

**Figure 5.1: Encoder high-level overview**

## 5.3.2 Input signal

The input signal $x(n)$ of the current frame $b$ consists of $N_F$ audio samples, $x(0), \ldots, x(N_F - 1)$ where the newest one is located at $x(N_F - 1)$. Audio samples of past frames are accessed by negative indexing, e.g. $x(-1)$ is the most recent sample of the previous frame.

The input signal $x(n)$ is typically retrieved in Pulse-Code-Modulation (PCM) format consisting of integer values in the range of $[-2^{s-1}, 2^{s-1}-1]$, where $s$ is the bit depth of the PCM input signal, e.g. 16, 24 or 32 bits per sample.

Any other audio format may need to be converted to match value scaling and data format.

## 5.3.3 Input signal scaling

The input signal is first scaled to the range [-32 768, 32 768] according to:

$$x_{s0}(n) = x_{clip}(n) \cdot 2^{-(s-1)+15} \tag{3}$$

where $s$ is the smallest integer such that $x_{s0}(n)$ fits in this range. E.g. for integer PCM format $s$ equals the bit-depths and for floating point PCM format $s$ is equal to 1. The scaled signal is subsequently clipped according to:

$$x_s(n) = \begin{cases} 2^{15}-1, & x_{s0}(n) > 2^{15}-1 \\ -2^{15}, & x_{s0}(n) < -2^{15} \\ x_{s0}(n), & otherwise \end{cases} \tag{4}$$

to fit the native 16 bit PCM range [-32 768, 32 767].

## 5.3.4 Low Delay MDCT analysis

### 5.3.4.1 Overview

The Low Delay Modified Discrete Cosine Transform (LD-MDCT) converts the audio input time domain samples into spectral coefficients and corresponding energy values grouped into bands. Figure 5.2 outlines the processing blocks.

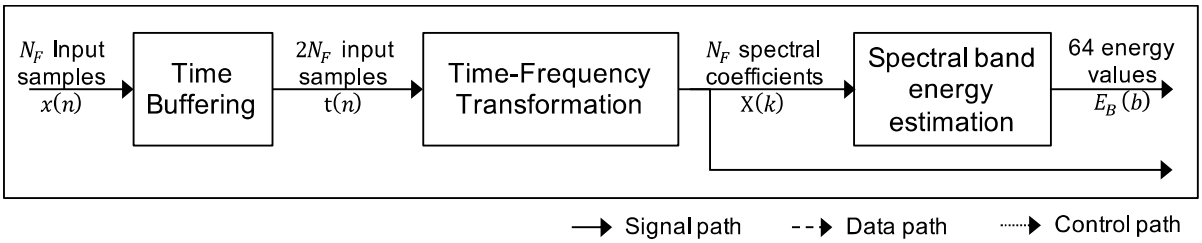

**Figure 5.2: Low delay MDCT overview**

### 5.3.4.2 Update time buffer

The time input buffer for the MDCT $t$ shall be updated according to:

$$\begin{aligned} t(n) &= x_s(Z - N_F + n)\ for\ \ n = 0 \ldots 2N_F - 1 - Z \\ t(2N_F - Z + n) &= 0 \quad for\ \ n = 0 \ldots Z - 1 \end{aligned} \tag{5}$$

where the latter initialization is typically jointly optimized with the subsequent time-frequency transformation.

### 5.3.4.3 Time-frequency transformation

A block of $N_F$ time samples is transformed to the frequency coefficients $X(k)$ using equation (6):

$$X(k) = \sqrt{\frac{2}{N_F}} \sum_{n=0}^{2N_F-1} w_{N_{ms}_N_F}(n) \cdot t(n) \cos\left[\frac{\pi}{N_F}\left(n + \frac{1}{2} + \frac{N_F}{2}\right)\left(k + \frac{1}{2}\right)\right] \ for\ k = 0 \ldots N_F - 1 \tag{6}$$

where $w_{N_{ms}_N_F}$ is the Low Delay MDCT window chosen for the frame size and length. The window has been optimized for $N_F = 480$ and all other versions with same $N_{ms}$ but different $N_F$ have been generated by means of interpolation. All window coefficients are given in clause 5.9.2. All windows with identical $N_{ms}$ are compatible to each other meaning that sampling rate conversion can be conducted as well.

The window shape is the result of an optimization algorithm, therefore there is no mathematical formula to calculate the coefficients. The optimization focused on exploiting the advantages of an asymmetric shape while keeping the temporal envelope close to one and providing a high stop-band attenuation. The result is given in Figure 5.3. As can be seen, the window shows two sections with an amplitude higher than one, which needs to be considered for fix-point implementations. The plot also shows the leading zeros $Z$ at the right side of the window.

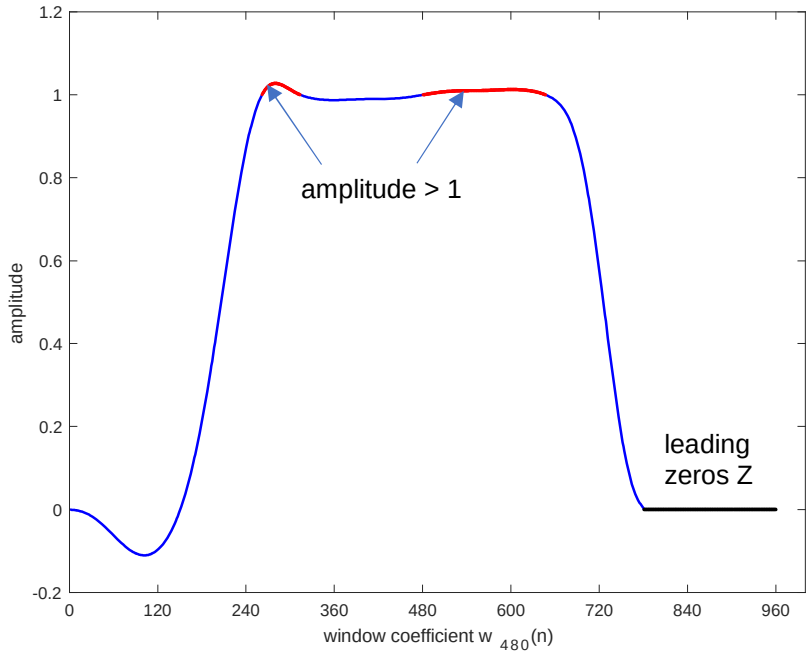

**Figure 5.3: Plot of low delay MDCT window $w_{10_480}$, sections greater than one are marked in red, leading zeroes are marked in black**

For $f_s = 48\ 000$ Hz, a maximum audio bandwidth of 20 kHz is encoded (about 18,4 kHz at $f_s = 44\ 100\ Hz$). The number of encoded frequency coefficients are defined as:

$$N_E = \min(N_F, 40 \cdot N_{ms}) \tag{7}$$

### 5.3.4.4 Energy estimation per band

The energy per band $E_B(b)$ is computed as follows:

$$E_B(b) = \sum_{k=I_{f_s}(b)}^{I_{f_s}(b+1)-1} \frac{X(k)^2}{I_{f_s}(b+1) - I_{f_s}(b)} \quad for\ b = 0 \ldots N_b - 1 \tag{8}$$

where $X(k)$ are the MDCT coefficients computed in clause 5.3.4.3, $N_b$ is the number of bands and $I_{f_s}(b)$ are the band indices given in clause 5.9.1.

## 5.3.4a Near Nyquist detector

The near Nyquist detector is used to identify signals with comparatively high energy in the range close to the Nyquist frequency. The near Nyquist detector is active only for sample rates $fs \leq 32\,000\ Hz$. The Aliasing-like structures in these signals can accidently trigger TNS and lead to distortions. To identify such signals the detector compares the energy of the upper and lower bands and sets the *near_nyquist_flag* to 1 if the following condition is fulfilled:

$$\sum_{n=nn_idx}^{n<N_b} E_B(n) \ > \ NN_{thresh} \cdot \sum_{n=0}^{n<nn_idx} E_B(n) \tag{8.1}$$

where $nn_idx$ is the highest band index of the considered energy bands as listed in Table 5.5a and $NN_{thresh}$ is 30. The *near_nyquist_flag* is handed over to the TNS module to deactivate TNS in case of a near Nyquist signal.

**Table 5.5a: $nn_idx$ and frame duration ($N_{ms}$)**

| $N_{ms}$ | $nn_idx$ |
|---|---|
| **2,5 ms** | $N_b - 2$ |
| **5 ms** | $N_b - 3$ |
| **7,5 ms** | $N_b - 4$ |
| **10 ms** | $N_b - 2$ |

For $N_{ms}$ = 1,25 ms, the near Nyquist detector is not required as TNS is turned off.

## 5.3.5 Bandwidth detector

### 5.3.5.1 Algorithm

This tool detects bandlimited signals coded at higher sampling rates, e.g. NB telephone call coded at 8 kHz but upsampled to a higher sampling rate. The detector provides guidance to the TNS (see clauses 5.3.8 and 5.4.6) and noise filling tool (see clauses 5.3.13 and 5.4.4) in order to avoid any spreading or smearing of noise into the empty upper spectrum. The quantization of the spectrum is not controlled by the BW detector to avoid any hard cut-offs in the spectrum in case of uncertain detections.

The detector is able to detect the commonly used speech bandwidths in voice communication, i.e. NB (0 kHz to 4 kHz), WB (0 kHz to 8 kHz), SSWB (0 kHz to 12 kHz), SWB (0 kHz to 16 kHz) and FB (0 kHz to 20 kHz). The definitions for NB, WB, SWB and FB are taken from the 3GPP EVS codec [i.1], where an audio bandwidth up to the Nyquist frequency is assumed. For the LC3plus, SSWB is defined in the present document as a 24 kHz sampled signal with an audio bandwidth up to the Nyquist frequency.

The bandwidth detector works as a two-stage classifier on the band energies $E_B$, as defined in clause 5.3.4.4. The first stage is designed to detect active bands. To this end, a sequence of low-energy flags $F_Q(k)$ is calculated for $k = 0 \ldots N_{bw} - 1$ as:

$$F_Q(k) = \begin{cases} 1 & , \ \sum_{n=I_{bw\,start}(k)}^{I_{bw\,stop}(k)} \frac{E_B(n)}{I_{bw\,stop}(k) - I_{bw\,start}(k) + 1} < T_Q(k) \\ 0 & , \ otherwise \end{cases} \tag{9}$$

$F_Q(-1)$ is defined to be 0. The values of $I_{bw\,start}(k)$ and $I_{bw\,stop}(k)$ are given in Table 5.6 and define frequency regions above the cut-off frequencies for the bandwidths in question. The quietness thresholds are given by $T_Q = \{20, 10, 10, 10\}$. The first stage classifier outputs a bandwidth index $bw_0$ which is the largest index between 0 and $N_{bw}$ (with 0 and $N_{bw}$ included) such that $F_Q(bw_0 - 1) = 0$.

The second stage determines the final bandwidth index $bw$. If $bw_0 = N_{bw}$, then $bw$ is set to $bw_0$. Otherwise, the second stage classifier aims at detecting an energy drop above the cut-off frequency of the candidate bandwidth $bw_0$. This is done by testing the condition:

$$\max_{I_{bw\,start}(bw_0)-L(bw_0)+1 \le n \le I_{bw\,start}(bw_0)+1} \left( 10log_{10}\left(\frac{E_B(n-L(bw_0))}{E_B(n)}\right)\right) > T_C(bw_0) \quad (10)$$

where $T_C = \{15, 23, 20, 20\}$ and $L = \{4, 4, 3, 1\}$ for 10 ms frame duration and $L$ = {4, 4, 3, 2} for 7,5 ms frame duration. If this condition holds then $bw$ is set to $bw_0$ and otherwise it is set to $N_{bw}$. The parameter $P_{bw}$ stores the value $bw$.

Considering the corrected bandwidth $B_c$ (clause 5.2.6), the bandwidth index $P_{bw}$ shall be adjusted to $P_{bwc}$:

$$P_{bwc} = min\left(P_{bw}, \frac{B_c}{4\,000} - 1\right) \quad (10.1)$$

If $B$ is set externally, the bandwidth detector may be skipped and the index calculated by $P_{bwc} = \frac{B_c}{4\,000} - 1$.

The bandwidth information (NB, WB, SSWB, SWB, FB) is retrieved by mapping $P_{bwc}$ to the bandwidth column in Table 5.6. The bandwidth information is used to control the TNS and the Noise level estimation. The parameter $P_{bwc}$ is stored in the bit stream using the number of bits $nbits_{bw}$ as outlined in Table 5.6.

### 5.3.5.2 Parameters

Table 5.6 lists the used parameters to detect the active bandwidth for a given sampling rate $f_s$ and frame duration $N_{ms}$.

**Table 5.6: Parameter table bandwidth detector**

| $N_{ms}$ | $f_s$ (Hz) | $N_{bw}$ | $I_{bw\,start}$ | $I_{bw\,stop}$ | Bandwidth ($P_{bwc}$) | $nbits_{bw}$ |
|---|---|---|---|---|---|---|
| 2,5 ms | 8 000 | 0 | - | - | {NB} | 0 |
| 2,5 ms | 16 000 | 1 | {24, 0, 0, 0} | {34, 0, 0, 0} | {NB, WB} | 1 |
| 2,5 ms | 24 000 | 2 | {24, 35, 0, 0} | {32, 39, 0, 0} | {NB, WB, SSWB} | 2 |
| 2,5 ms | 32 000 | 3 | {24, 33, 39, 0} | {31, 38, 42, 0} | {NB, WB, SSWB, SWB} | 2 |
| 2,5 ms | 44 100, 48 000 | 4 | {22, 31, 37, 41} | {29, 35, 40, 43} | {NB, WB, SSWB, SWB, FB} | 3 |

| 7,5 ms | 8 000 | 0 | - | - | {NB} | 0 |
| 7,5 ms | 16 000 | 1 | {51, 0, 0, 0} | {63, 0, 0, 0} | {NB, WB} | 1 |
| 7,5 ms | 24 000 | 2 | {45, 58, 0, 0} | {55, 63, 0, 0} | {NB, WB, SSWB} | 2 |
| 7,5 ms | 32 000 | 3 | {42, 53, 60, 0} | {51, 58, 63, 0} | {NB, WB, SSWB, SWB} | 2 |
| 7,5 ms | 44 100, 48 000 | 4 | {40, 51, 57, 61} | {48, 55, 60, 63} | {NB, WB, SSWB, SWB, FB} | 3 |
| 10 ms | 8 000 | 0 | - | - | {NB} | 0 |
| 10 ms | 16 000 | 1 | {53, 0, 0, 0} | {63, 0, 0, 0} | {NB, WB} | 1 |
| 10 ms | 24 000 | 2 | {47, 59, 0, 0} | {56, 63, 0, 0} | {NB, WB, SSWB} | 2 |
| 10 ms | 32 000 | 3 | {44, 54, 60, 0} | {52, 59, 63, 0} | {NB, WB, SSWB, SWB} | 2 |
| 10 ms | 44 100, 48 000 | 4 | {41, 51, 57, 61} | {49, 55, 60, 63} | {NB, WB, SSWB, SWB, FB} | 3 |

Note that when $f_s = 8\,000\,Hz$, the bandwidth detector is not needed and then the assignments $P_{bwc} = 0$ and $nbits_{bw} = 0$ are made, i.e. the parameter $P_{bwc}$ is not stored in the bit stream.

For $N_{ms}$ = 1,25 ms, the near bandwidth detector is disabled, $nbits_{bw}$ is set to zero and $P_{bwc}$ is always set to the maximum bandwidth, e.g. FB for $f_s$= 48 kHz.

## 5.3.6 Time Domain Attack Detector

### 5.3.6.1 Overview

The time domain attack detector is active only when one of the following conditions is satisfied:

- $f_s = 32\,000\,Hz,\ N_{ms} = 10$ and $80 < nbytes < 340$
- $f_s \geq 44\,100\,Hz,\ N_{ms} = 10$ and $100 \leq nbytes < 340$
- $f_s = 32\,000\,Hz,\ N_{ms} = 7{,}5\ and\ 61 \leq nbytes < 150$
- $f_s \geq 44\,100\,Hz,\ N_{ms} = 7{,}5\ and\ 75 \leq nbytes < 150$

If active, the transient detector outputs a flag $F_{att}(k)$ for each frame $k$, which takes values 1, indicating that an attack was detected, or 0, indicating that no attack was detected in this frame. If not active, $F_{att}(k)$ is set to 0. In the following, the start-up frame index is denoted $k_0$.

For $N_{ms}$ = 1,25 ms, the time domain attack detector is disabled and $F_{att}(k)$ of (16) is 0.

### 5.3.6.2 Downsampling and Filtering of Input Signal

The first step is a downsampling of the input signal $x_s(n), n = 0 \ldots N_F - 1$, which is performed as:

$$x_{att}^{(k)}(n) = \sum_{m=0}^{\frac{N_F}{160}-1} x_s\left(\frac{N_F}{160}n + m\right)\ for\ n = 0 \ldots 159 \tag{11}$$

Next, the downsampled signal is high pass filtered according to:

$$x_{hp}^{(k)}(n) = 0{,}375\ x_{att}^{(k)}(n) - 0{,}5\ x_{att}^{(k)}(n-1) + 0{,}125\ x_{att}^{(k)}(n-2), for\ n = 0 \ldots 159 \tag{12}$$

As in the case of the input signal, samples at negative indices correspond to samples from previous frames, i.e. $x_{att}^{(k)}(-1)$ and $x_{att}^{(k)}(-2)$ hold the values $x_{att}^{(k-1)}(159)$ and $x_{att}^{(k-1)}(158)$. The values $x_{att}^{(k_0)}(-1)$ and $x_{att}^{(k_0)}(-2)$ are defined to be zero.

### 5.3.6.3 Energy Calculation

The attack detector operates on block wise energies on four blocks of 40 samples.

$$E_{att}^{(k)}(n) = \sum_{l=40n}^{40n+39} x_{hp}^{(k)}(l)^2, for\ n = 0 \ldots 3 \tag{13}$$

which are compared to a delayed long term temporal envelope which is inductively defined by:

$$A_{att}^{(k)}(n) = \max\left\{0{,}25\ A_{att}^{(k)}(n-1),\ E_{att}^{(k)}(n-1)\right\}, for\ n = 0 \ldots 3 \tag{14}$$

where the values at index -1 correspond again to the values at index 3 in frame $k-1$. The values $A_{att}^{(k_0)}(-1)$ and $E_{att}^{(k_0)}(-1)$ are defined to be zero.

### 5.3.6.4 Attack Detection

An attack is detected if:

$$E_{att}^{(k)}(n) > 8{,}5\ A_{att}^{(k)}(n) \tag{15}$$

holds for any *n* between 0 and 3. Furthermore, in this case the attack position $P_{att}(k)$ is defined to be the largest n such that the inequality holds. Otherwise, $P_{att}(k)$ is set to -1. The value $P_{att}(k_0 - 1)$ is defined to be -1.

The attack flag for frame $k$ is computed as:

$$F_{att}(k) = \begin{cases} 1 & if\ P_{att}(k)\ \geq 0\ or\ P_{att}(k-1) \geq 2, \\ 0 & else. \end{cases} \quad (16)$$

## 5.3.7 Spectral Noise Shaping

### 5.3.7.1 Overview

Spectral Noise Shaping (SNS) applies a set of scale factors to the MDCT spectrum. These scale factors shape the quantization noise introduced in the frequency domain by the spectral quantization. The noise shaping is performed in such a way that the quantization noise is minimally perceived by the human ear, maximizing the perceptual quality of the decoded output.

The SNS encoder performs the following four steps. A set of 16 scale factors is first estimated as described in clause 5.3.7.2. These 16 scale factors are then quantized and encoded as described in clause 5.3.7.3. The quantized scale factors are then interpolated as described in clause 5.3.7.4. Finally, the MDCT spectrum is shaped using the 64 interpolated scale weights as described in clause 5.3.7.5. Figure 5.4 outlines the processing steps.

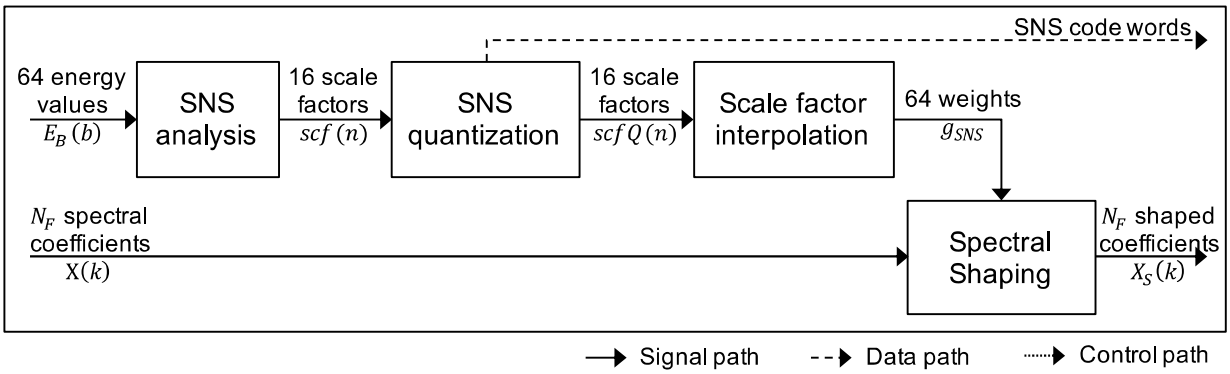

**Figure 5.4: SNS encoder overview**

### 5.3.7.2 SNS analysis

#### 5.3.7.2.1 Overview

In the first step of the SNS encoder, a set of 16 scale factors are estimated. These scale factors are derived from the 64 energies per band $E_B(b)$ (see clause 5.3.4.4). In case, the codec is configured to operate on less than 64 bands $N_B$, the given energy values are padded to get exactly 64 energies per band $E_B(b)$.

#### 5.3.7.2.2 Padding

In case the configuration of the codec results in a number of bands $N_B < 64$, the energy array $E_B(b)$ is extended by repeating the entries, starting from the lowest ones, until the vector has reached its dedicated size of 64. Two cases need to be considered.

For $N_B < 32$, the lowest values need to be repeated four times and the higher ones two times.

```
n4=round(abs(1-32/N_B)* N_B)
n2 = N_B - n4

for i=0..n4-1
    for i2=0..3
        E_B2(i*4+i2) = E_B(i);

for i=0..n2-1
    for i2=0..1
        E_B2((n4-1)*2+i*2+i2) = E_B((n4-1)+i);
```

For $N_B$ < 64, some lower values need to be repeated twice:

```
n2 = 64 -N_B

for i=0..n2-1
    for i2=0..1
        E_B2(i*2+i2) = E_B(i);

for i=0.. N_B
        E_B2((n2-1)*2+i) = E_B((n2-1)+i);
```

Finally, all 64 extrapolated values in $E_{B2}$ are copied back to $E_B$ and used for further processing.

#### 5.3.7.2.3 Smoothing

The energy per band $E_B(b)$ is first smoothed using:

$$E_S(b) = \begin{cases} 0{,}75 \cdot E_B(0) + 0{,}25 \cdot E_B(1) & , if\ b = 0 \\ 0{,}25 \cdot E_B(62) + 0{,}75 \cdot E_B(63) & , if\ b = 63 \\ 0{,}25 \cdot E_B(b-1) + 0{,}5 \cdot E_B(b) + 0{,}25 \cdot E_B(b+1) & , otherwise \end{cases} \quad (17)$$

#### 5.3.7.2.4 Pre-emphasis

A long term normalized autocorrelation is calculated by:

$$\mathrm{LT}_{\mathrm{normcorr}} = 0{,}125 \cdot \mathrm{normcorr} + 0{,}875 \cdot \mathrm{LT}_{\mathrm{normcorr}} \quad (17.1)$$

where normcorr is calculated according to (87) and $\mathrm{LT}_{\mathrm{normcorr}}$ is initialized to 0,5. $\mathrm{LT}_{\mathrm{normcorr}}$ controls an adaptive component of the pre-emphasis depending on the harmonicity of the audio signal in order to emphasize the low frequencies compared to the high frequencies. The harmonicity measure $\mathrm{F}_{\mathrm{preempasis}}$ is given by:

$$\mathrm{F}_{\mathrm{preempasis}} = \begin{cases} \max(\mathrm{LT}_{\mathrm{normcorr}} - 0{,}8;\ 0) \cdot 5 & \text{for } N_{ms} = 1{,}25 \text{ and } f_s \in [32\,000, 48\,000] \\ 0 & else \end{cases} \quad (17.2)$$

The smoothed energy per band $E_S(b)$ is then pre-emphasized using, by controlling the tilt value based on the harmonicity measure:

$$E_P(b) = E_S(b) \cdot \left(10^{\frac{b \cdot g_{tilt}}{10 \cdot 63}} + \mathrm{F}_{\mathrm{preempasis}} \cdot 10^{\frac{b \cdot 1{,}4 \cdot g_{tilt}}{10 \cdot 63}}\right) \ for\ b = 0 \ldots 63 \quad (18)$$

with $g_{tilt}$ given in Table 5.7.

**Table 5.7: Pre-emphasis tilt factor table**

| $f_s$ (Hz) | $g_{tilt}$ |
|---|---|
| 8 000 | 14 |
| 16 000 | 18 |
| 24 000 | 22 |
| 32 000 | 26 |
| 44 100, 48 000 | 30 |

#### 5.3.7.2.5 Noise floor

A noise floor at -40 dB is added to $E_P(b)$ using:

$$E_{P2}(b) = \max(E_P(b), noiseFloor) \ \ for\ b = 0 \ldots 63 \quad (19)$$

with the noise floor being calculated by:

$$noiseFloor = \max\left(\frac{\sum_{b=0}^{63} E_P(b)}{64} \cdot 10^{-\frac{40}{10}}, 2^{-32}\right) \quad (20)$$

#### 5.3.7.2.6 Logarithm

A transformation into the logarithm domain is then performed using:

$$E_L(b) = \frac{\log_2\left(E_{P2}(b)\right)}{2} \quad for\ b = \ 0 \ldots 63 \tag{21}$$

#### 5.3.7.2.7 Band Energy Grouping

The vector $E_L(b_1)$, with $b_1 \in [0, 63]$ is then grouped and decimated by a factor of 4 using:

$$E_4(b_2) = \begin{cases} w(0)E_L(0) + \sum_{k=1}^{5} w(k)\, E_L(4b_2 + k - 1) & , if\ b_2 = 0 \\ \sum_{k=0}^{4} w(k)\, E_L(4b_2 + k - 1) + w(5)E_L(63) & , if\ b_2 = 15 \\ \sum_{k=0}^{5} w(k)\, E_L(4b_2 + k - 1) & , otherwise \end{cases} \tag{22}$$

with $b_2 \in [0, 15]$, and

$$w(k) = \left\{\frac{1}{12}, \frac{2}{12}, \frac{3}{12}, \frac{3}{12}, \frac{2}{12}, \frac{1}{12}\right\} \tag{23}$$

#### 5.3.7.2.8 Mean removal and scaling, attack handling

For $N_{ms}$ = 1,25 ms, a limiter gain $sns_{lim}$ is calculated by:

$$limiter_{score} = \ \min\left(\max\left(\frac{2 \cdot (E_4(0) - E_4(1)) + (E_4(0) - E_4(2))}{2}, 5\right), 8\right) \tag{23.1}$$

$$sns_{lim} = \ 0{,}7 \ \cdot \frac{8 - limiter_{score}}{3} + 0{,}3 \tag{23.2}$$

For all other frame durations, $sns_{lim} = 1$.

Mean removal and scaling is performed according to:

$$scf_0(b_2) = sns_{lim} \ \cdot 0{,}85\left(E_4(b_2) - \frac{\sum_{b=0}^{15} E_4(b)}{16}\right) \ for\ b_2 = \ 0 \ \ldots \ 15. \tag{24}$$

If the attack detection is not active or if it is active and $F_{att}(k) = 0$, then the final scale factors are given by:

$$scf(n) = scf_0(n)\ for\ n = 0 \ldots 15. \tag{25}$$

For $N_{ms}$ = 1,25 ms, an additional mild smoothing is applied as a three-tap FIR filter:

$$\propto_k = \left\{\frac{10}{16}, \frac{3}{16}\right\}, for\ k = 0 \ \ldots \ 1 \tag{25.1}$$

$$scf_1(-1) = \left(scf_0(0) + scf_0(1)\right) \cdot \frac{1}{2}, \tag{25.2}$$

$$scf_1(16) = \left(scf_0(14) + scf_0(15)\right) \cdot \frac{1}{2}, \tag{25.3}$$

$$scf_1(n) = \sum_{k=-1}^{1} \propto_{|k|} scf_0(n + k) \ for\ n = 0 \ldots 15, \tag{25.4}$$

For $N_{ms} \neq 1{,}25$ ms and if attack detection is active and $F_{att}(k) = 1$, a relatively strong additional smoothing is applied as a three to five tap FIR filter to the scale factors according to:

$$scf_1(0) = \frac{1}{3}\left(scf_0(0) + scf_0(1) + scf_0(2)\right), \tag{26}$$

$$scf_1(1) = \frac{1}{4}\left(scf_0(0) + scf_0(1) + scf_0(2) + scf_0(3)\right), \tag{27}$$

$$scf_1(n) = \frac{1}{5}\sum_{m=-2}^{2} scf_0(n+m) \;\; for\; n = 2 \ldots 13, \tag{28}$$

$$scf_1(14) = \frac{1}{4}\left(scf_0(12) + scf_0(13) + scf_0(14) + scf_0(15)\right), \tag{29}$$

and

$$scf_1(15) = \frac{1}{3}\left(scf_0(13) + scf_0(14) + scf_0(15)\right). \tag{30}$$

From these smoothed values the final scale factors are computed as:

$$scf(n) = f_{att} \cdot \left(scf_1(n) - \frac{\sum_{b=0}^{15} scf_1(b)}{16}\right) \;\; for\; n = \; 0 \; \ldots \; 15. \tag{31}$$

where $f_{att} = 0{,}5$ if $N_{ms} = 10$, and $f_{att} = 0{,}3$ if $N_{ms} = 7{,}5$.

### 5.3.7.3 SNS quantization

#### 5.3.7.3.1 General

The SNS scale factors *scf(n)* (obtained in clause 5.3.7.2) are quantized using a two-stage vector quantizer employing a total of 38 bits (R = 2,375 bits/coefficient), the first stage is a 10 bit split VQ and the second stage is a low complexity algorithmic Pyramid Vector Quantizer (PVQ). To further maintain low overall VQ complexity the Pyramid VQ is analysed in a gain/shape manner in a transformed domain, enabling an efficient shape only search, followed by a low complexity total MSE evaluation in a combined gain and shape determination step. In general, PVQ quantizers are a family of L1-norm based algorithmic vector quantizers, employing very little storage space and utilizing an algorithmic structure that enables efficient search procedures. A general background to PVQ may be found in [i.2], however note that the actual PVQ-search and indexing method in the present document is different from what is described in that reference.

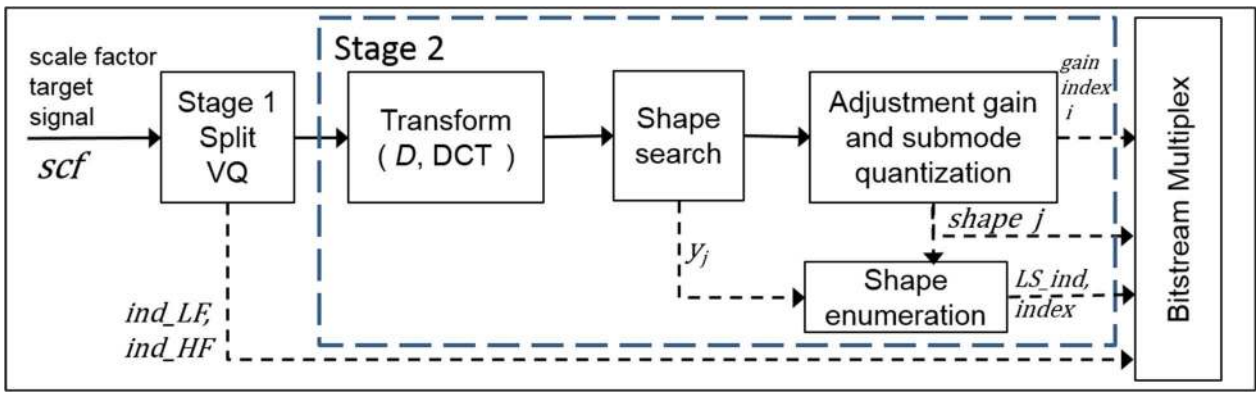

**Figure 5.5: High level overview of Encoder SNS VQ analysis**

#### 5.3.7.3.2 Stage 1

The first stage is a split VQ employing two off-line trained stochastic codebooks *LFCB* and *HFCB*. Each codebook row has dimension 8 and the number of codebook columns is limited to 32, requiring 5 bits for each split for transmission. The MSE distortions for the two code books are defined as follows:

$$dMSE_{LF_i} = \sum_{n=0}^{7} \left( scf(n) - LFCB_i(n) \right)^2 \tag{32}$$

$$dMSE_{HF_i} = \sum_{n=0}^{7} \left( scf(n+8) - HFCB_i(n) \right)^2 \tag{33}$$

The best index for the low-frequency split is found according to:

$$ind_LF = \underset{i=[0 \ldots 31]}{\operatorname{argmin}} \; dMSE_LF_i \tag{34}$$

The best index for the high-frequency split is found according to:

$$ind_HF = \underset{i=[0 \ldots 31]}{\operatorname{argmin}} \; dMSE_HF_i \tag{35}$$

Codebooks *LFCB* and *HFCB* may be searched in any order.

The first stage vector is composed as:

$$st1(n) = LFCB_{ind_LF}(n), \qquad for\ n = [0 \ldots 7], \tag{36}$$

$$st1(n+8) = HFCB_{ind_HF}(n), \qquad for\ n = [0 \ldots 7]. \tag{37}$$

The first stage residual signal is calculated as:

$$r1(n) = scf(n) - st1(n), \qquad for\ n = [0 \ldots 15]. \tag{38}$$

#### 5.3.7.3.3 Stage 2

##### 5.3.7.3.3.1 General

On a high level the overall mean square error that is minimized by the second stage is:

$$dMSE(shape_j, gain_i, LSindices, MPVQindices) = \sum_n \left( r1_n - G_{gain_i,shape_j} \cdot \left[ x_{q,shape_j,n}(LSindices, MPVQindices) \cdot \boldsymbol{D^T} \right] \right)^2 \tag{39}$$

where $G_{gain_i,shape_j}$ is a scalar value, $\boldsymbol{D}$ is a 16-by-16 rotation matrix (realizing an IDCT rotation) and $x_{q,shape_j}$ is a unit energy normalized vector of length 16. The $shape_j, gain_i, LSindices, MPVQindices$ are vector quantization sub-indices that results in a total of $\boldsymbol{2^{28}}$ possible gain-shape combinations. The target of the second stage SNS VQ search is to find the set of indices that results in a minimum $dMSE$ distortion value.

Depending on the selected shape index $shape_j$ the number of leading sign indices $LSindices$ are one {$LS_indA$} or two {$LS_indA, LS_indB$}, and similarly depending on the selected shape index $shape_j$ the number of $MPVQindices$ are one {$idxA$} or two {$idxA, idxB$}.

##### 5.3.7.3.3.2 Transform

The second stage employs a 16-dimensional DCT-rotation using a 16x16 matrix $D$. The $\boldsymbol{D}$-matrix has been determined off-line for efficient scale factor quantization, it has the property that $D^T D = I$ (the identity matrix). To reduce the encoder side search complexity the reverse (analysis) transform $D\ (= DCT)$ may be used prior to the shape and gain determination, while on the decoder side only the forward (synthesis) transform $D^T$ (=$IDCT$) is required. The coefficients of the full $D$ rotation matrix are listed in clause 5.9.3, here it should be noted that one may also use the equivalent conventional $DCT$ (realized as the orthogonalized DCT-II) and the corresponding $IDCT$ functions to realize these transformations.

#### 5.3.7.3.3.3 Stage 2 Target Preparation

The shape search target preparation consists of a 16x16 dimensional matrix analysis rotation. An orthogonalized DCT-II is implemented using matrix multiplication with 16x16 matrix $\boldsymbol{D}$, where the DCT base vectors are stored column wise as:

$$t2_{rot}(n) = \sum_{row=0}^{15} r1(row) \cdot \boldsymbol{D}(n + row \cdot 16) \ , \qquad where\ n = [0 \dots 15] \tag{40}$$

#### 5.3.7.3.3.4 Shape Candidates

There are four different 16-dimensional unit energy normalized shape candidates evaluated, where the normalization is always performed over 16 coefficients. The pulse configurations for two sets *(A and B)* of scale factors for each candidate shape index (***shape_j***) are given in Table 5.8.

**Table 5.8: SNS VQ second stage shape candidate pulse configurations**

| Shape index (*shape_j*) | Shape name | Scale factor set A | Scale factor set B | Pulse configuration, Set A, PVQ($N_A$, $K_A$) | Pulse configuration, Set B, PVQ($N_B$, $K_B$) |
|---|---|---|---|---|---|
| 0 | 'regular' | {0, 1, 2, 3, 4, 5, 6, 7, 8, 9} | {10, 11, 12, 13, 14, 15} | PVQ(10, 10) | PVQ(6, 1) |
| 1 | 'regular_lf' | {0, 1, 2, 3, 4, 5, 6, 7, 8, 9} | {10, 11, 12, 13, 14, 15} | PVQ(10, 10) | *Zeroed* |
| 2 | 'outlier_near' | {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15} | Empty set | PVQ(16, 8) | *Empty* |
| 3 | 'outlier_far' | {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15} | Empty set | PVQ(16, 6) | *Empty* |

The shape index $shape_j = 0$ pulse configuration is a hybrid PVQ shape configuration, with $K_A$=10 over $N_A$=10 scale factors and $K_B$=1 over the remaining $N_B$=6 scale factors. For shape index 0, it should be noted that the two sets of unit pulses are unit energy normalized over the full target dimension $N=N_A+N_B$=16, even though the PVQ integer pulse and sign enumeration is performed separately for each scale factor set.

#### 5.3.7.3.3.5 Stage 2 Shape Search

The goal of the *PVQ(N, K)* shape search procedure is to find the best normalized vector $x_q(n)$. In vector notation $x_q(n)$ is defined as:

$$\boldsymbol{x_q} = \frac{\boldsymbol{y}}{\sqrt{\boldsymbol{y^T y}}} \tag{41}$$

where $y = y_{N,K}$ belongs to *PVQ(N, K)* and this integer vector is a deterministic point on the surface of an N-dimensional hyper-pyramid with K unit pulses. The L1-norm of $y_{N,K}$ is $K$, in other words, $y_{N,K}$ is an integer shape code vector of dimension $N$ according to:

$$\boldsymbol{y_{N,K}} = \left\{ \boldsymbol{e} \quad : \quad \sum_{\boldsymbol{n=0}}^{\boldsymbol{N-1}} |\boldsymbol{e_n}| = \boldsymbol{K} \right\} \tag{42}$$

As a result of the definition, $x_q$ is a unit energy normalized integer vector $\mathbf{y}_{N,K}$, a deterministic point on the N-dimensional non-integer unit energy hypersphere. A high $K$ value leads to a better shape approximation over dimension $N$ but also has a higher cost in terms of bit rate, for transmitting the location of the $K$ unit pulses in the vector of dimension $N$.

The best integer $\boldsymbol{y}$ vector is the one minimizing the mean squared shape error between the second stage target vector $t2_{rot}(n) = x(n)$ and the normalized quantized output vector $x_q$. The shape search is achieved by minimizing a distortion measure according to equation (43), where the shape distortion measure $d_{PVQ-shape}$ is obtained by assuming an optimal gain in equation (39).

$$d_{PVQ-shape} = -\boldsymbol{x}^T\boldsymbol{x_q} = -\frac{(\boldsymbol{x}^T\boldsymbol{y})}{\sqrt{\boldsymbol{y}^T\boldsymbol{y}}} \tag{43}$$

By squaring the numerator and denominator in equation (43) one may also maximize the quotient $Q_{PVQ\text{-}shape}$:

$$Q_{PVQ-shape} = \frac{(\boldsymbol{x}^T\boldsymbol{y})^2}{\boldsymbol{y}^T\boldsymbol{y}} = \frac{\left(corr_{xy}\right)^2}{energy_y} \tag{44}$$

where $corr_{xy}$ is the correlation between vector $x$ and vector $y$. One may also use an efficient iterative search method in the all positive hyperoctant in $N$-dimensional space. In such a search in the all positive hyper-octant for the best (in an MSE sense) always positive integer vector $\boldsymbol{y}$, the correlation $corr_{xy}$ and $energy_y$ terms may always be evaluated as vector products $(|\boldsymbol{x}|^T\boldsymbol{y})$ and $\boldsymbol{y}^T\boldsymbol{y}$, respectively. However with the unit pulse iterative approach**,** the search for the optimal (in an MSE sense) PVQ vector shape $y(n)$ with L1-norm $K$, may be simplified using iterative updates of the $Q_{PVQ\text{-}shape}$ variables for each unit pulse position candidate $n_c$ according to:

$$corr_{xy}(k, n_c) = corr_{xy}(k-1) + 1 \cdot |x(n_c)| \tag{45}$$

$$energy_y(k, n_c) = energy_y(k-1) + 2 \cdot 1^2 \cdot y(k-1, n_c) + 1^2 \tag{46}$$

where $\mathrm{corr}_{xy}(k\text{-}1)$ signifies the correlation achieved so far by placing the previous $k\text{-}1$ positive unit pulses, $energy_y(k\text{-}1)$ signifies the accumulated energy achieved so far by placing the previous $k\text{-}1$ positive unit pulses, and $y(k\text{-}1, n_c)$ signifies the amplitude of $y$ at position $n_c$ from the previous placement of a total of $k\text{-}1$ unit pulses. When no previous pulses have been placed, $y$ is an all zero vector and thus $corr_{xy}$ is zero, and hence also $energy_y$ is zero.

$$Q_{PVQ-shape}(k, n_c) = \frac{\left(corr_{xy}(k, n_c)\right)^2}{energy_y(k, n_c)} \tag{47}$$

The best position $n_{best}$ for the $k_{\text{th}}$ unit pulse, is iteratively updated by increasing $n_c$ from $0$ to $N\text{-}1$:

$$n_{best} = n_c, \quad if\ Q_{PVQ-shape}(k, n_c) > Q_{PVQ-shape}(k, n_{best}) \tag{48}$$

To avoid divisions (which is especially important in fixed point arithmetic) the $Q_{PVQ\text{-}shape}$ maximization update decision may be performed using a cross-multiplication of a saved best squared correlation numerator $bestCorrSq$ so far and the saved best energy denominator $bestEn$ so far.

$$\left.\begin{array}{rcl} n_{best} & = & n_c \\ bestCorrSq & = & corr_{xy}(k, n_c)^2 \\ bestEn & = & energy_y(k, n_c) \end{array}\right\}, if\ corr_{xy}(k, n_c)^2 \cdot bestEn > bestCorrSq \cdot energy_y(k, n_c) \tag{49}$$

It should be noted that the pulse search methodology has to increase the number of pulses for each unit pulse addition loop, i.e. one shall force at least one update of $n_{best}$ over the positions $0$ to $N\text{-}1$ in equation (48) or in the cross-multiplied version equation (49).

The iterative maximization in the all positive hyperoctant of $Q_{PVQ\text{-}shape}(k, n_c)$ may start from a zero number of initially placed unit pulses ($y_{start}(n) = 0$, for $n = 0 \ldots 15$) or alternatively from a low cost pre-placement number of unit pulses based on a projection to an integer valued point below the $K$th-pyramid's surface, with a guaranteed undershoot of unit pulses in the target L1 norm $K$. Such a projection may be made as follows:

$$proj_{fac} = \frac{K-1}{\sum_{n=0}^{n=15}|t2_{rot}(n)|} \tag{50}$$

$$y_{start}(n) = \left\lfloor |t2_{rot}(n)| \cdot proj_{fac} \right\rfloor, \qquad for\ n = 0 \ldots 15 \tag{51}$$

If a projection is used in combination with an iterative positive unit pulse search approach one will need to calculate $corr_{xy}(k-1)$ as $(|\boldsymbol{x}|^T\boldsymbol{y_{start}})$ and $energy_y(k-1)$ as $\boldsymbol{y_{start}}^T\boldsymbol{y_{start}}$ before commencing the unit pulse addition iterations.

Four signed integer pulse configurations vectors $y_j$ are established by using the distortion measure $d_{PVQ-shape}$ and then their corresponding unit energy shape vectors $x_{q,j}$ are computed according to equation (41).

In the $j = 0$ search, the set B positions only contain a single non-stacked unit pulse with a fixed energy contribution, this means that the search for the single pulse in set B may be simplified to search only for the maximum absolute value in the six set B locations.

For the $j = 0,1$ normalization, each total pulse configuration $y_j$ always spans 16 coefficients. Hence, the energy normalization is always performed over dimension 16, even though two shorter position sets are used for enumeration of the $y_0$ integer vector and one position set (set A) of dimension 10 for the $y_1$ integer vector.

An efficient overall unit pulse search (for all four shape candidates) may be achieved by searching the shapes in the order from shape $j = 3$ to shape $j = 0$, by making a first projection to a point on or below the pyramid $K = 6$, updating the correlation and energy terms, and then sequentially adding unit pulses and saving intermediate shape results until $K$ is correct for each of the four shape candidates with a higher number of unit pulses $K$. Note that as the regular set A shapes $j = 0,1$ spans over different allowed scale factor dimensions/regions than the two outlier shapes ($j = 2,3$), one will need to handle the search start pulse configuration for the two regular shapes by removing any unit pulses which are not possible to index in the regular shape set A($j = 0,1$). As the described iterative pulse search is performed in the all positive hyperoctant, a final step of setting the signs of the non-zero entries in $y_j(n)$ based on the corresponding sign in target vector $x(n) = t2_{rot}(n)$ is performed.

A step-by-step example of a search procedure is shown in Table 5.9 and example of resulting vectors are shown in Table 5.10.

**Table 5.9: Informational example of a PVQ search strategy for the described PVQ based shapes**

| Search step | Related shape index ($j$) | Description of search step | Resulting vector |
|---|---|---|---|
| 1 | 3 | Project to or below pyramid N = 16, K = 6, (and update energy $energy_y$ and correlation $corr_{xy}$ terms to reflect the pulses present in $y_{3,\,start}$) | $y_{3,\,start}$ |
| 2 | 3 | Add unit pulses until K = 6 is reached over N = 16 samples, save $y_3$ | $y_3 = y_{2,\,start}$ |
| 3 | 2 | Add unit pulses until K = 8 is reached over N = 16 samples, save $y_2$ | $y_2 = y_{1,\,pre\text{-}start}$ |
| 4 | 1 | Remove any unit pulses in $y_{1,\,pre\text{-}start}$ that are not part of set A to yield $y_{1,\,start}$ | $y_{1,\,start}$ |
| 5 | 1 | Update energy $energy_y$ and correlation $corr_{xy}$ terms to reflect the pulses present in $y_{1,\,start}$ | $y_{1,\,start}$ (unchanged) |
| 6 | 1 | Add unit pulses until K = 10 is reached over N = 10 samples (in set A), save $y_1$ | $y_1 = y_{0,\,start}$ |
| 7 | 0 | Add unit pulses to $y_{0,\,start}$ until K = 1 is reached over N=6 samples (in set B), save $y_0$ | $y_0$ |
| 8 | 3, 2, 1, 0 | Add signs to non-zero positions of each $y_j$ vector from the target vector $x$, save $y_3, y_2, y_1, y_0$ as shape vector candidates (and for subsequent indexing of one of them) | $y_3, y_2, y_1, y_0$ |
| 9 | 3, 2, 1, 0 | Unit energy normalize each $y_j$ vector to candidate vector $x_{q,j}$ | $x_{q,3}, x_{q,2}, x_{q,1}, x_{q,0}$ |

**Table 5.10: Informational example of potentially available integer vectors $y_j$ and their corresponding unit energy normalized vectors $x_{q,j}$, after completing the PVQ search**

| Shape index ($j$) | Example Integer vector $y_j$ | Corresponding unit energy normalized vector $x_{q,j}$ (NB! Shown in very low precision here) |
|---|---|---|
| 0 | $y_0$ = [-10, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1] | $x_{q,0}$ = [-0,995, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 100] |
| 1 | $y_1$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 10, 0, 0, 0, 0, 0, 0] | $x_{q,1}$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 1,0, 0, 0, 0, 0, 0, 0] |
| 2 | $y_2$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, -7] | $x_{q,2}$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0,141, 0, 0, 0, 0, 0, -0,990] |
| 3 | $y_3$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1, 1, -1, 1, -1, 1] | $x_{q,3}$ = [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -0,408, 0,408, -0,408, 0,408, -0,408, 0,408] |

#### 5.3.7.3.3.6 Adjustment Gain Candidates

There are four different adjustment gain candidate sets, one set corresponding to each overall shape candidate *j*. The adjustment gain configuration for each of the shapes are given in Table 5.11.

**Table 5.11: SNS VQ Second Stage Adjustment Gain sets**

| Gain set index (same as Shape index = *j*) | Corresponding Shape name | Number of gain levels | Adjustment Gain set values ($G_{i,j}$) See clause 5.9.3 | Start adjustment gain index $Gminind_j$ | End adjustment gain index $Gmaxind_j$ |
|---|---|---|---|---|---|
| 0 | 'regular' | 2 | sns_vq_reg_adj_gains[2] | 0 | 1 |
| 1 | 'regular_lf' | 4 | sns_vq_reg_lf_adj_gains[4] | 0 | 3 |
| 2 | 'outlier_near' | 4 | sns_vq_near_adj_gains[4] | 0 | 3 |
| 3 | 'outlier_far' | 8 | sns_vq_far_adj_gains[8] | 0 | 7 |

#### 5.3.7.3.3.7 Shape and Gain combination determination

The best possible shape and gain is determined among the possible shape candidates and each corresponding gain set. To minimize complexity the Mean Square Error (MSE) versus the target may be evaluated in the rotated domain, i.e. the same domain in which the shape search was performed.

$$dMSE(j,i) = \sum_{n=0}^{15} (t2_{rot}(n) \quad - \quad G_{i,j}\, x_{q,j}(n))^2, \qquad for\ j = 0 \ldots 3, i = 0 \ldots Gmaxind_j \tag{52}$$

Out of the total *18(2+4+4+8)* possible gain-shape combinations, the shape_index *shape_j* and adjustment gain index *gain_i* that results in the minimum MSE is selected for subsequent enumeration and multiplexing.

$$\{shape_j = j\,, gain_i = i\} = \underset{j=0\ \ldots\ 3,\ \ i=0 \ldots Gmaxind_j}{\operatorname{argmin}} dMSE(j,i) \tag{53}$$

#### 5.3.7.3.3.8 Enumeration of the selected PVQ pulse configurations

The pulse configuration(s) of the selected shape are enumerated using an efficient scheme which separates each *PVQ(N, K)* pulse configuration into two short codewords: a leading sign index bit and an integer MPVQ-index codeword. The MPVQ-index bit-space is typically fractional (i.e. a non-power of 2 total number of pulse configurations). The indexing step may also be referred to as enumeration.

The largest sized MPVQ integer shape index (*shape_j = 2*, 'outlier_near') fits within a 24 bit unsigned word, enabling fast implementations of MPVQ enumeration and de-enumeration on platforms supporting unsigned integer arithmetic of 24 bits or higher.

The enumeration scheme uses an indexing offsets table *MPVQ_offsets(n, k)* which may be found as a table of unsigned integer values in clause 5.9.3. The offset values in *MPVQ_offsets* (dimension n, L1-norm k) are defined recursively as:

$$MPVQ_offsets(n,k) = MPVQ_offsets(n-1,k-1) + MPVQ_offsets(n,k-1) + MPVQ_offsets(n-1,k), \tag{54}$$

with initial conditions *MPVQ_offsets (n, k = 0) = 0 for n>= 0, MPVQ_offsets (n = 0, k) =1 for k>0.*

The actual enumeration of a signed integer vector *y* (=*vec_in)* with an L1 norm of ***K*** (=*k_val_in)* over dimension *N* (=*dim_in)* into an MPVQ shape index *index* and a leading sign index *lead_sign_ind* is shown in C-style pseudo code below:

```
[ index, lead_sign_ind ] =
MPVQenum  ( dim_in,      /* I :  dimension of vec_in       */
            vec_in[N]    /* i :  PVQ integer pulse train   */
{
    /*  init    */
    next_sign_ind  =  0x80000000U;  /* sentinel for first sign  */
    k_val_acc = 0;
    pos       = dim_in;
    index     = 0;
    n         = 0;
    row_ptr   = &(MPVQ_offsets[n]);

    /* MPVQ-index composition loop */
```

```
    tmp_h_row = row_ptr[0];
    for (pos--; pos >= 0; pos--) {
        tmp_val               = vec_in[pos];
        [index, next_sign_ind] = encPushSign(tmp_val, next_sign_ind, index);
        index                 += tmp_h_row;
        k_val_acc             += abs(tmp_val);

        if ( pos != 0 ) {
           n += 1;       /* switch row in offset table MPVQ_offsets(n, k) */
        }
        row_ptr   = &(MPVQ_offsets[n]);
        tmp_h_row = row_ptr[k_val_acc];
    }
    lead_sign_ind = next_sign_ind;

    return [ index, lead_sign_ind ] ;
}

[ index, next_sign_ind ] =
encPushSign( val, next_sign_ind_in, index_in)
{
    index = index_in;
    if ((next_sign_ind_in & 0x80000000U) == 0) && (val != 0) {
        index = 2*index_in + next_sign_ind_in;
    }
    next_sign_ind = next_sign_ind_in;
    if ( val < 0 ) {
        next_sign_ind = 1;
    }
    if ( val > 0 ){
        next_sign_ind = 0;
    }
    /* if val==0, there is no new sign information to "push",
       i.e. next_sign_ind is not changed */
    return [ index, next_sign_ind ];
}
```

The `MPVQ_enum()` function above implements a PVQ-enumeration method that passes through all the possible combinations of signed elements given the input signed integer PVQ-vector `vec_in`, while sequentially pushing one bit of sign information from the end of the vector (`pos = dim_in-1`) towards the front (`pos = 0`). The function `encPushSign`() stores the information about the other non-leading signs in the larger of two codewords. This enumeration method enables a separation of a large total PVQ-index into two shorter separate codewords.

The following MPVQ enumeration calls are made for a selected shape_*j*.

**Table 5.12: Scale factor VQ second stage shape enumeration *of* integer vector $y_{shape_j}$ *into MPVQ shape indices{idxA, idxB}, and leading signs indices{LS_indA, LS_indB}* for each possible *selected* shape index *shape_j***

| Shape index (*shape_j*) | Shape name | Scale factor set A enumeration | Scale factor set B enumeration |
|---|---|---|---|
| 0 | 'regular' | *[idxA , LS_indA]* = MPVQenum(*10, 10,* $y_0$) | $z(n\text{-}10) = y_0(n)$, *for n=10...15* *[idxB, LS_indB]* = MPVQenum(*6, 1, z*) |
| 1 | 'regular_lf' | *[idxA, LS_indA]* = MPVQenum(*10, 10,* $y_1$) | n/a |
| 2 | 'outlier_near' | *[idxA, LS_indA]* = MPVQenum(*16, 8,* $y_2$) | n/a |
| 3 | 'outlier_far' | *[idxA, LS_indA]* = MPVQenum(*16, 6,* $y_3$) | n/a |

### 5.3.7.3.4 Multiplexing of SNS VQ Codewords

The SNS VQ Stage 1 codewords are multiplexed in the following order: $ind_LF$(5 bits) followed by $ind_HF$(5 bits).

The second stage SNS VQ codeword multiplexing is performed differently depending on the selected shape *shape_j*.

To efficiently use the available 38 bits for the second stage SNS scale factor quantizer, the fractional sized MPVQ-indices, the LSB of shape index *j*, the second stage shape codewords and potentially an LSB of the gain codeword are jointly encoded. The overall parameter encoding order for the second stage multiplexing components is shown in Table 5.13.

**Table 5.13: Multiplexing order and parameters for the second stage**

| SNS-VQ Multiplexing order | Stage 2 parameter description | Parameter |
|---|---|---|
| 0 | Stage 2 submode bit | *shape_j>>1, (as the submodeMSB bit)* |
| 1 | Gain index *gain_i* or MSBs of the adjustment gain index *gain_i* | *gain_i ,* (the gain index), for even(*shape_j*) (or *gain_i>>1*; for odd (*shape_j*) |
| 2 | Leading sign of shape in set A | $LS_indA$ |
| 3 | A joint shape index (for set A and set B) and possibly an LSB gain bit | Joint composition of : $(idxA, LS_indB, idxB, LSB_{submode}, LSB_{gain})$ The LSB submode bit is encoded as a bitspace section inside the overall joint shape codeword $index_{joint}$ |

In the multiplexing of leading signs $LS_indA$ and/or $LS_indB$, each leading sign is multiplexed as 1 if the leading sign is negative and multiplexed as a 0 if the leading sign is positive.

**Table 5.14: Submode bit values, sizes of the various second stage MPVQ shape indices, and the adjustment gain separation sections for each shape index (=*shape_j*)**

| Shape index (*shape_j*) | Shape name | Submode bit value (regular/ outlier) | $SZ_{MPVQ}$ Set A (excl. $LS_indA$) | $SZ_{MPVQ}$ Set B (excl. $LS_indB$) | Number of LSB gain index code points | Adjustment gain index bit separation {MSBs, LSB} |
|---|---|---|---|---|---|---|
| 0 | 'regular' | 0 | $SZ_{shapeA,0}$ = 2 390 004 (~21,1886 bits) | $SZ_{shapeB,0}$ = 6 (~2,585 bits) | 0 | {1, 0} |
| 1 | 'regular_lf' | 0 | $SZ_{shapeA,1}$ = $SZ_{shapeA,0}$ | $SZ_{shapeB,1}$ = 1 (0 bits) | 2 | {1, 1} |
| 2 | 'outlier_near' | 1 | $SZ_{shapeA,2}$ = 15 158 272 (~23,8536 bits) | n/a | 0 | {2, 0} |
| 3 | 'outlier_far' | 1 | $SZ_{shapeA,3}$ = 774 912 (~19,5637 bits) | n/a | 2 | {2, 1} |

In Table 5.14 one can find that each logical shape index *shape_j* also represents a combination of a vector shape and an allocation of gain adjustment bits {MSBs, LSB} for that logical index. Each of the four different of gain-shape coding schemes have different trade-offs in gain resolution (ranging from 1 to 3 bits per residual vector) and in shape resolution (ranging from ~1,22 to ~2,11 bits per residual coefficient), thus enabling the second stage SNS-VQ to represent signals requiring both high shape resolution and signals requiring a high dynamic range.

Encoding of gain or MSBs of gains:

For a selected shape with shape index *shape_j* = 0 and *shape_j* = 2, *submodeLSB* is set to 0, and the selected gain index is sent without modification as index gain_i, for gain value $G_{gain_i,shape_j}$, requiring 1 bit for *shape_j* = 0 and 2 bits for *shape_j* = 2.

For a selected shape with shape index *shape_j* = 1 and *shape_j* = 3, *submodeLSB* is set to1, and for a selected gain value $G_{gain_i,shape_j}$ with gain index i, the MSB part of the gain index is first obtained by a removal of the $LSB_{gain}$ bit. I.e. $gain_i_{MSBs} = gain_i >> 1$; $LSB_{gain} = gain_i \,\&0x1$. The multiplexing of $gain_i_{MSBs}$ will require 1 bit for *shape_j* = 1 and 2 bits for *shape_j* = 3. The $LSB_{gain}$ bit will be multiplexed into the joint index.

Joint index composition:

Joint index for a selected shape index of *shape_j* = 0 ('regular') and *submodeLSB* = 0

$$index_{joint,0} = (2 \cdot idxB + LS_{indB} + 2) \cdot SZ_{shapeA,0} + idxA \quad (55)$$

where the range of *idxB* is from 0 to ($SZ_{shapeB,0}$ - 1).

Joint index for a selected shape index of $shape_j = 1$ ('regular_lf') and $submodeLSB = 1$

$$index_{joint,1} = LSB_{gain} \cdot SZ_{shapeA,1} + idxA \quad (56)$$

as $log2(SZ_{shapeB,1}) = 0$ bits are required for set B, $idxB$ is not multiplexed into $index_{joint,1}$.

Joint index for a selected shape index of $shape_j = 2$ ('outlier_near') and $submodeLSB = 0$

$$index_{joint,2} = idxA \quad (57)$$

Joint index for a selected shape index of $shape_j = 3$ ('outlier_far') and $submodeLSB = 1$

$$index_{joint,3} = SZ_{shapeA,2} + LSB_{gain} + 2 \cdot idxA \quad (58)$$

#### 5.3.7.3.5 Synthesis of the Quantized SNS scale factor vector

The quantized first stage vector $st1$, the quantized second stage unit energy shape vector $x_{q,shape_j}$, the quantized adjustment gain $G_{gain_i,shape_j}$ (with gain index $gain_i$), and the rotation matrix $\boldsymbol{D}$ (now used to implement the synthesis IDCT transform) are used to establish the quantized scale factor vector $scfQ(n)$ as follows:

$$scfQ(n) = st1(n) \quad + \quad G_{gain_i,shape_j} \cdot \sum_{col=0}^{15} \left[ x_{q,shape_j}(col) \cdot \boldsymbol{D}(col + n \cdot 16) \right], for\ n = 0 \ldots 15 \quad (59)$$

### 5.3.7.3a Low Rate SNS quantization

#### 5.3.7.3a.1 Low Rate SNS VQ General

The Low Rate SNS scale factors $scf(n)$ (obtained in clause 5.3.7.2) are quantized using a one or a two-stage variable rate vector quantizer. The available bit rates are R = {0,5625, 0,625, 1,8125, 1,875} bits/coefficient, corresponding to employing a total of 9, 10, 29 or 30 bits. The first stage is based on three variations of trained 16 dimensional codebooks ($CB_A$, $CB_B$, $CB_C$) and the second stage are gain-shape structured VQ's employing two algorithmic concepts for the shape; Pyramid Vector Quantization (PVQ) and Fixed Envelope Shifted Signs (FESS) quantization. Figure 5.5a gives an overview of the encoder side analysis flow. Figure 5.5b depicts the bitstream multiplexing structure for the available Low Rate SNS quantization modes.

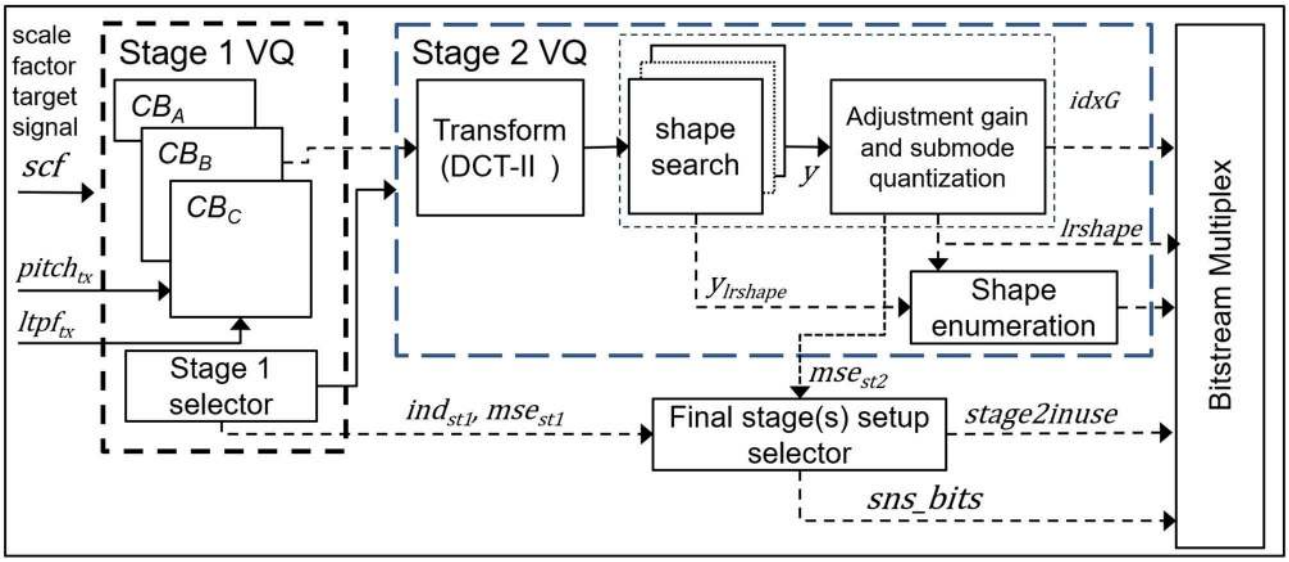

**Figure 5.5a: High level overview of Encoder Low Rate SNS VQ analysis**

| Mode | Stage1<br>16-dimensional gain and shape | Stage2<br>15 dimensional, gain-shape VQ in DCT-II domain | | LR SNS bits<br>(incl. VBR multiplexing) |
|---|---|---|---|---|
| Stage 1 A only | $CB_A$<br>[ 2 entries ] | | | 9b |
| Stage 1 B only | $CB_B$<br>[ 170 entries ] | | | 10b |
| Stage 1 C only | $CB_C$<br>[ 3 x 170 entries] | | | 10b<br>(supported by $pitch_{tx}$, $ltpf_{tx}$) |
| *Stage 1+2*<br>*lrsns* == 0a | $CB_B$ as Stage 1<br>[170 entries] | 2b gain | { PVQ(N=5, K=6) AND PVQ(N=8, K=2) } | 29b |
| *Stage 1+2*<br>*lrsns* == 0b | | | PVQ(N=5, K=8) | |
| *Stage 1+2*<br>*lrsns* ∈ { 1 } | | 3b Gain | PVQ(N=15, K=5) | 30b |
| *Stage 1+2*<br>*lrsns* ∈ {2 … 5} | | | { FESS(N=15, $N_s$=12) OR FESS(N=13, $N_s$=10) } | |

**Figure 5.5b: High level overview of the variable rate Low Rate SNS VQ mode multiplexing structure**

### 5.3.7.3a.2 Low Rate SNS VQ Stage 1

The first stage is a $M = 16$ dimensional VQ employing three different off-line trained stochastic codebooks *($CB_A$, $CB_B$, $CB_C$)*. Each codebook vector has dimension *M* and the number of codebook vectors $N_i$ are 2, 170 and 170 respectively for $i \in \{A, B, C\}$. The MSE distortion for a vector *j* in one of the three codebooks is defined as follows:

$$dMSE_{CB_{i,j}} = \sum_{n=0}^{15} \left( scf(n) - CB_{i,j}(n) \right)^2 , for\ i \in \{A, B, C\}, \qquad j \in \{0 \dots N_i - 1\} \tag{59.1}$$

The best index in the MSE sense for each first stage codebooks is found according to:

$$ind_i = \underset{j=[0 \ldots N_i-1]}{\operatorname{argmin}} dMSE_{CB_{i,j}} \tag{59.2}$$

#### 5.3.7.3a.2.1 Stage 1 Code book A search and synthesis

Codebook $CB_A$ consists of two SNS vectors where one $CB_{A,0}$ is the an all zero vector corresponding to equal noise shaping across frequency bands for the frame, and a second vector $CB_{A,1}$ which corresponds to applying an inversed and dynamically compressed absolute hearing threshold curve for the frame. The stored representation of both vectors is prequantized in steps of 1 / 2 048 to enable high precision interoperability between floating and fixed point implementations.

The best vector of $CB_{A,0}$ and $CB_{A,1}$ is denoted $CB_{A,ind_A}$ and the related mean squared error is thus $dMSE_{CB_{A,ind_A}}$. Eventually if $CB_A$ is selected it is jointly multiplexed as a part of the initial stage one 9-bit index $idx_{SNSLR0}$, where value 510 corresponds to vector $CB_{A,0}$ and value 511 corresponds to vector $CB_{A,1}$.

5.3.7.3a.2.2 Stage 1 Code book B search and synthesis

The set of vectors of the second codebook $CB_B$ consists of $N_B$ order permutations and polarity reversal of the regular SNS stage one codebook vectors in $LFCB\ and\ HFCB$ quantized into steps of 1 / 2 048, these are denoted as $LFCB_{Q11}\ and\ HFCB_{Q11}$. Each vector in $CB_B$ is compactly represented by a 14 bit lookup index $SNSB_{idx}$, $idx \in [0 \ldots N_b\text{-}1]$**,** stored within a 16 bit integer and thus only $N_B \cdot 2 = 340$ bytes are required to store the whole configuration of $CB_B$ (assuming that the tables $LFCB_{Q11}\ and\ HFCB_{Q11}$ are already available). When stored in a fully expanded format, the $CB_B$ would require 5,44 kB.

**Table 5.14a: Information within each stored idxB14b index**

| $\boldsymbol{SNSB_{idx}}$ bit position | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| multiplexed information | LF-reversal | HF-reversal | LF-sign | HF-sign | index in $LFCB_{Q11}$ | | | | | index in $HFCB_{Q11}$ | | | | |

Each SNS vector $SNSVECB_{idx}$ of length 16 is created by parsing $\boldsymbol{SNSB_{idx}}$ as follows:

The bits in section b9 to b5 are used to extract the initial vector $SNSVECB_{LF}$ of length $\frac{M}{2}$ from $LFCB_{Q11}$,and the bits in section b4 to b0 are used to extract the initial vector $SNSVECB_{HF}$ of length $\frac{M}{2}$ from $LFCB_{Q11}$. If ***b13*** is set then the $\frac{M}{2}$ elements in $SNSB_{LF}$ are reversed and additionally if ***b11*** is set the polarity of the elements in $SNSB_{LF}$ is reversed. If ***b12*** is set then the $\frac{M}{2}$elements in $SNSVECB_{HF}$ are reversed and additionally if ***b10*** is set the polarity of the elements in $SNSVECB_{HF}$ is reversed. The resulting modified vectors $SNSVECB_{LF}$ and $SNSVECB_{HF}$ are then concatenated into a 16 element long $SNSVECB_{idx}$vector.

The search of codebook $CB_B$ is on a high level performed by iterating through the sequence of $N_B$ $SNSB_{idx}$ formatted indices**,** creating each 16 element vector $SNSVECB_{idx}$ and minimizing the MSE across all indices according to equation (59.2), with $SNSVECB_{idx}, idx \in [0 \ldots N_B - 1]$as $CB_B$. The order of the $N_B$ formatted lookup indices have been optimized offline to reduce the $CB_B$ indirect lookup search complexity, by grouping the lookup index transformations into a list of elements with 88 initial indices with {b13, b12} ={0, 0}, followed by 42 indices with {b13, b12} ={1,0}, followed by 24 indices with {b13, b12} ={0, 1} and finally followed by 16 indices with {b13, b12} ={1,1}. This ordering of $CB_B$ vectors enables an efficient search in four segments, where the LF and/or HF part of target signal is conditionally reversed instead of reversing each partial codebook vector for every index. The final winning index from the $CB_B$ MSE search is denoted $ind_B$.

Due to the reuse of combined $LFCB_{Q11}\ and\ HFCB_{Q11}$ vectors, an undesired DC component may be added to the initially selected codebook vector $SNSVECB_{ind_B}$ with index $ind_B \in [0 \ldots N_B\text{-}1]$. The DC component is removed after the search using a DC removal function with a predetermined precision of 1 / 2 048 as follows:

$$DC_{BQ11} = \left\lfloor \frac{\sum_{n=0}^{15} SNSVECB_{ind_B}(n)}{16} \right\rfloor \tag{59.3}$$

$$CB_{B,ind_B}(\mathrm{n}) = SNSVECB_{ind_B}(n) - DC_{BQ11}, \text{for n} \in [0 \ldots \text{M-1}] \tag{59.4}$$

Additionally the MSE obtained from the $SNSVECB_{idx}$ search is updated, to exclude the error contribution from $DC_{BQ11}$.

$$dMSE_{CB_{B,indB}} = \left| dMSE_{CB_{B,indB}} - DC_{BQ11}{}^2 \cdot M \right| \tag{59.5}$$

where the absolute value is needed to avoid negative energy values due to potential rounding errors in the DC calculation.

The final index $CB_{B,ind_B}\ with\ ind_B \in [0 \ldots N_B\text{-}1]$ is later conditionally multiplexed into the 9 bit $idx_{SNSLR0}$ as a value in the range $[0 \ldots N_B\text{-}1]$ or in the range $[2 \cdot N_B \ldots 3 \cdot N_B\text{-}1]$.

#### 5.3.7.3a.2.3 Codebook C search and synthesis

The stage1 codebook C search is only performed if the minimum of stage 1 A and stage 1 B distortion is larger than 1,5 dB in Spectral Distortion (SD), (corresponding to a SNS domain MSE of 3,97). I.e. the stage 1 C codebook search is skipped if $minimum(dMSE_{CB_{A,indA}} \cdot \propto, dMSE_{CB_{B,indB}}) > 3{,}97\ ,\ where\ \propto$ is 0,875. If codebook C search was not performed and the index $ind_C$ for stage 1 C was not calculated, then set $ind_C\ to\ 0$ and the distortion value $dMSE_{CB_{C,indC}}$ to $2 \cdot 3{,}97$.

The set of vectors of the third codebook $CB_C$ consists of $N_C$ vectors trained on critical instrumental harmonic music outliers in relation to the two previous codebooks $CB_A$ and $CB_B$. The codebook utilizes the correlation with the earlier transmitted pitch information, $pitch_{tx}$ (==*pitch_present*) and $ltpf_{tx}$ (==*ltpf_active*) such that one out of three possible $CB_C$ mean vectors is initially selected and applied based on the available pitch information.

$$mean_{C,Q11}(\mathrm{n}) = \begin{cases} CBCmeanp0(n) & , \quad pitch_{tx} == 0 \\ CBCmeanp1(n) & , \quad pitch_{tx} == 1 \ \cap ltpf_{tx} == 0, \ for\ n = 0\,..\,M\text{-}1 \\ CBCmeanp2(n) & , \quad pitch_{tx} == 1 \ \cap ltpf_{tx} == 1 \end{cases} \tag{59.6}$$

**Table 5.14b: Pitch information dependent SNS mean vectors used for $CB_C$**

| Name | $pitch_{tx}$ value | $ltpf_{tx}$ value | Mean vector values quantized into the S16Q11 domain |
|---|---|---|---|
| $CBCmeanp0$ | 0 | 0 | { 2 293, 2 602, 1 960, 1 161, 880, 417, 34, -169,<br>-368, -541, -604, -318, -287, -958, -2 341, -3 760 } / 2 048 |
| $CBCmeanp1$ | 1 | 0 | { -3 680, -3 482, -2 787, -1 918, -1 130, -747, 883, 2 199,<br>2 742, 2 742, 2 885, 3 181, 3 022, 1 835, -1 015, -4 730 } / 2 048 |
| $CBCmeanp2$ | 1 | 1 | { -4 600, -4 353, -3 484, -2 397, -1 413, -933, 1 103, 2 749,<br>3 428, 3 428, 3 606, 3 976, 3 777, 2 293, -1 268, -5 912 } / 2 048 |

A local $CB_C$ SNS residual target $scfr_{Q11}$ is prepared as:

$$scfr_{Q11}(n) = scf(n) - mean_{C,Q11}(\mathrm{n})\,, \text{for n} = 0\ \ldots\ M\text{-}1 \tag{59.7}$$

The residual vectors within the $CB_C$ codebook are stored in a S8Q7 format in $CB_{Cres}$, where each SNS coefficient is represented by a byte with possibles integer values ranging from -128 to +127, resulting an a ROM table size for $CB_C$ of 2,7 kB. In the synthesis of the vector for a given $CB_C$ codebok index $idx_C$ an additional predetermined scaling factor $scaleCQ4$ with an integer value of 86 and a fractional value of 86/16 == 5,375 brings the stored byte values to the target SNS residual domain with a precision of 1 / 2 048 steps.

$$scfr_{Cres,ind_C}(n) = scaleCQ4 \cdot CB_{Cres,idx_C}(\mathrm{n})\,, \text{for n} = 0\ \ldots\ \mathrm{M\text{-}1} \tag{59.8}$$

The target for the $CB_C$ MSE search loop the residual signal vector $scfr_{Q11}$ is normalized into vector $scfr_{S8Q7}$ by the factor $invScaleCQ15$ (with an integer value of 6 096 and a fractional value of 6 096 / 2 048 == 0,18603515625) to enable an efficient search in the S8Q7 domain.

$$scfr_{Q7}(n) = invscaleCQ15 \cdot scfr_{Q11}(n)\,, \text{for n} = 0\ \ldots\ \mathrm{M\text{-}1} \tag{59.9}$$

The inner loop MSE distortion calculation for codebook $CB_C$ corresponding to equations (32) and (34) is performed in a downscaled mean residual domain:

$$dMSE_{CB_{Cres,j}} = \sum_{n=0}^{\mathrm{M}-1} \left(scfr_{Q7}(n) \ - \ CB_{Cres,j}(n)\right)^2, \qquad j \ \in \{0 \ldots N_C\text{-}1\ ) \tag{59.10}$$

The best index is selected according to:

$$ind_{\mathrm{C}} = \underset{j=[\,0\ \ldots\ N_C-1]}{\operatorname{argmin}} dMSE_{CB_{Cres,j}} \tag{59.11}$$

Finally the final $CB_C$ vector is generated in 1 / 2 048,0 precision as:

$$CB_{C,ind_C}(\mathrm{n}) = \ mean_{C,Q11}(\mathrm{n}) + scaleCQ4 \cdot CB_{Cres,ind_C}(\mathrm{n}),\ for\ n = 0\,..\,\mathrm{M\text{-}1} \tag{59.12}$$

And the outer MSE error is calculated according to:

$$dMSE_{CB_{C,indC}} = scaleCQ4^2 \cdot dMSE_{CB_{Cres,indC}} \tag{59.13}$$

The final index $CB_{C,ind_C}$ $with\ ind_C \in [0 \ldots N_C\text{-}1]$ is later conditionally multiplexed into the 9 bit $idx_{SNSLR0}$ as a value in the range $[0 \ldots N_C\text{-}1]$ or in the range $[N_C \ldots (2 \cdot N_C)\text{-}1]$.

#### 5.3.7.3a.2.4 Low Rate Residual Calculation

In preparation for a possible stage 2 search, the LR SNS first stage residual signal based on $CB_{B,indB}$ is calculated as:

$$r1_{\mathrm{SNSLR}}(n) = scf(n) - CB_{B,indB}(n), \qquad for\ n = [0 \ldots 15]. \tag{59.14}$$

### 5.3.7.3a.3 Low Rate SNS-VQ Stage 2

#### 5.3.7.3a.3.1 General

The LRSNS stage 1 B codebook may be followed by a second VQ stage in case the spectral distortion is not low enough in stage 1 to match the target spectral shape. When the distortion for the best codebook of stage 1 {A, B, C} is lower than 1,75 dB in terms of Spectral Distortion (corresponding to $dMSE_{CB_{stage1}} \leq 5{,}41$ ), then the Low Rate SNS-VQ Stage 2 search is not performed at the encoder side.

The overall mean square error that is minimized by the low rate SNS second stage is:

$$dMSE(lrshape, idxG, SHAPEindices) = \sum_n \left(r1_{SNSLR,n} - G_{gain_{\mathrm{idxG}},lrshape} \cdot \left[x_{q,\mathrm{lrshape},n}(SHAPEindices) \cdot \boldsymbol{D^T}\right]\right)^2 \tag{59.15}$$

Where $G_{gain_{\mathrm{idxG}},\mathrm{lrshape}}$ is a scalar value, $\boldsymbol{D}$ is a 16-by-16 rotation matrix (realizing an IDCT-II rotation) and $x_{q,\mathrm{lrshape},n}$ is a unit energy normalized vector of length 16. The $lrshape, idxG, SHAPEindices$ are vector quantization sub-indices that results in a total of $\boldsymbol{2^{20}}$ to $\boldsymbol{2^{21}}$ possible gain and shape combinations. The target of the second stage LR SNS vector quantization search is to find the shape *lrshape*, the gain $gain_{idxG}$ and a set of *SHAPEindices* that results in a minimum $dMSE$ distortion value.

Depending on the selected shape index *lrshape* , the *SHAPEindices* is either a set of 15 dimensional MPVQ (Modular Pyramid VQ) indices, or a set of 15 dimensional FESS (Fixed Envelope Shifted Signs) indices. The quantized DCT-II domain DC value $x_{q,lrhape,0}$ is always zero in the Low Rate SNS case. I.e. the Low Rate SNS second stage does not correct any DC error from the preceding first stage.

#### 5.3.7.3a.3.2 Transform

Same transform as in clause 5.3.7.3.3.2 is applied.

#### 5.3.7.3a.3.3 Stage 2 Target Preparation

Same target preparation as in clause 5.3.7.3.3.

#### 5.3.7.3a.3.4 Stage 2 Shape Candidates

There are seven different 16-dimensional unit energy normalized shape candidates evaluated, where the normalization is always performed over 16 coefficients. The pulse configurations for two sets *(A* and *B)* of scale factors for each candidate shape index (***lrshape***) are given in Table 5.14c. The position indices of each set *{A, B}* corresponds to a segment of scale factor coefficients in the stage 2 target.

**Table 5.14c: LR SNS VQ second stage shape candidate pulse configurations**

| Shape index (*lrshape*) | Shape name | Position indices for scale factor set A | Position indices for scale factor set B | Pulse configuration, Set A PVQ($N_A$, $K_A$) | Pulse configuration, Set B, PVQ($N_B$, $K_B$) |
|---|---|---|---|---|---|
| 0a | 'LR_splitLF' | {1, 2, 3, 4, 5} | {6, 7, 8, 9, 10, 11, 12, 13} | PVQ(5, 6) | PVQ(8, 2) |
| 0b | | | | PVQ(5, 8) | *Empty* |
| 1 | 'LR_full' | {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15} | Empty set | PVQ(15, 5) | *Empty* |
| 2 | 'LR_Fix-0' | {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15} | Empty set | FESS(N=15, $N_S$=12) | *Empty* |
| 3 | 'LR_Fix-I' | | | | |
| 4 | 'LR_Fix-II' | | | | |
| 5 | 'LR_Fix-III' | {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13} | | FESS(N=15, $N_S$=10) | |

The initial shape configurations ($lrshape \in \{0a, 0b, 1\}$employ stacked unit pulses, according to the Pyramid VQ principles. The final four shapes use FESS pulse configurations. i.e. $lrshape \in \{2, 3, 4, 5\}$ use non-stacked unit pulses and requires a lower bit rate than the stacked PVQ pulse configurations.

The first two low rate shapes (0a and 0b) are focussed on minimizing the distortion for lower frequencies and are denoted 'LR_splitLF'. The $lrshape = 0a$ uses two PVQ pulse configurations over a total of 13 (5 + 8) SNS residual values, the first set, setA, is used to quantize 5 SNS residual values with 6 unit pulses using a $PVQ(N_A = 5, K_A = 6)$, starting from $r1_{\mathrm{SNSLR}}(1)$ ,and ending with $r1_{\mathrm{SNSLR}}(5)$. The second set, set B, is used to quantize 8 SNS residual values with 2 unit pulses using a $PVQ(N_B = 8, K_B = 2)$, starting from $r1_{\mathrm{SNSLR}}(6)$, and ending with $r1_{\mathrm{SNSLR}}(13)$. The $lrshape = 0b$) uses one PVQ pulse configuration over a total of 5 SNS residual values, the first set, *set A*, is used to quantize 5 SNS residual values with 8 unit pulses using a $PVQ(N_A = 5, K_A = 8)$, starting from $r1_{\mathrm{SNSLR}}(1)$,and ending with $r1_{\mathrm{SNSLR}}(5)$.

Residual coefficients $r1_{\mathrm{SNSLR}}(0)$, $r1_{\mathrm{SNSLR}}(14)$ and $r1_{\mathrm{SNSLR}}(15)$ are not encoded for the 'LR_splitLF' shape 0a, additionally for shape 0b $r1_{\mathrm{SNSLR}}(6)$ through $r1_{\mathrm{SNSLR}}(13)$ are not encoded . The 'LR_splitLF' shapes can be represented by $\mathrm{N}_{0a} = \mathrm{N}_{a0,A} \cdot \mathrm{N}_{0a,B}$ and $\mathrm{N}_{0b} = \mathrm{N}_{0b,A} \cdot 1$ combinations, where $\mathrm{N}_{0a,A} = \mathrm{N}_{\mathrm{MPVQ}}(PVQ(5,6)) = 1970$, $\mathrm{N}_{0a,B} = \mathrm{N}_{\mathrm{MPVQ}}(PVQ(8,2)) = 128$ and $\mathrm{N}_{0b,A} = \mathrm{N}_{\mathrm{MPVQ}}(PVQ(5,8)) = 5\,890$ . Correspondingly the bit consumption for 'LR_splitLF' is $\mathrm{B}_0 = \log2(\mathrm{N}_{0a,A} \cdot \mathrm{N}_{0a,B} + \mathrm{N}_{0b,A})$, thus $\mathrm{B}_0 = 17{,}977$ bits, these 'LR_splitLF' 0a and 0b bits are later multiplexed over a total of 18 whole integer bits.

The third low rate shape uses an evenly spread distortion minimization over the full bandwidth (all coefficients) and is denoted 'LR_full' ($lrshape = 1$), and uses a single PVQ pulse configuration over a total of 15 SNS residual values, the first and only set, set A, is used to quantize the residual values with 5 unit pulses using a $PVQ(N_A = 15, K_A = 5)$, starting from $r1_{\mathrm{SNSLR}}(1)$ , and ending with $r1_{\mathrm{SNSLR}}(15)$. The DC residual coefficient $r1_{\mathrm{SNSLR}}(0)$ is not encoded for the 'LR_full' shape. The 'LR_full' shape can be represented by $\mathrm{N}_1 = \mathrm{N}_{1,A}$ combinations, where $\mathrm{N}_{1,A} = \mathrm{N}_{\mathrm{MPVQ}}(PVQ(15,5)) = 207\,006$. Correspondingly the bit consumption for 'LR_full' is $\mathrm{B}_1 = \mathrm{B}_{1,A}$ where $\mathrm{B}_{1,A} = \log2(\mathrm{N}_{1,A}) = 17{,}6593$ bits. The remaining coding space up to a whole of 18 bits is $N_{1,A,residual} = 2^{18} - N_{1,A} = 55138$. This remaining codingspace $B_{1,A,residual} = log2(N_{1,A,residual}) = 15{,}75\ bits$ is used for multiplexing the FESS-envelope index for the four FESS shapes $lrshape \in \{2, 3, 4, 5\}$, as four separate multiplexing FESS sections after the initial $\mathrm{N}_{1,A}$ 'LR_full' entry.

The remaining low rate shapes employ a FESS "Fixed Envelope Shifted Signs" low complex enumeration concept, the FESS shapes are here also denoted 'Fix', with a sub index 0,I,II,III. Each of these four fixed envelope shapes have a different potential SNS envelope specified across coefficients 1 to 15, and do not allow further stacking of unit pulses. The four available fixed envelopes are:

**Table 5.14d: Envelopes used for flat shapes $lrshape \in \{2, 3, 4, 5\}$**

| lrshape | envIdx | Envelope name | Envelope integer vector $y_{envIdx,shift}$ values for residual coefficients 1 through 15 | Description |
|---|---|---|---|---|
| 2 | 0 | $Fix-0$ | lrsns_fix_env_fx [0][0 …14] = {8, 8, 8, 7, 7, 6, 6, 5, 5, 5, 5, 5, 5, 5, 5} | Initial bell envelope, integer levels, 12 signs |
| 3 | 1 | $Fix-I$ | lrsns_fix_env_fx [1][0 …14] = {12, 12, 11, 11, 10, 10, 9, 9, 8, 8, 7, 7, 6, 6, 5} | LF to HF decaying envelope, integer levels, 12 signs |
| 4 | 2 | $Fix-II$ | lrsns_fix_env_fx [2][0 …14] = {7, 7, 8, 8, 8, 7, 7, 6, 6, 5, 5, 5, 5, 5, 5} | Bell envelope, integer levels, 12 signs |
| 5 | 3 | $Fix-III$ | lrsns_fix_env_fx [3][0 …14] = {6, 6, 7, 7, 8, 8, 8, 7, 7, 6, 6, 5, 5, 5, 5} | Delayed bell envelope, integer levels, 10 signs |

Consecutive segments of the envelopes above of length $N_s = 12$ or $N_s = 10$, are normalized into unit energy vectors, using the table values FESS_inv_sqrt_en below:

**Table 5.14e: Envelope energy normalization values used for fixed shapes $lrshape \in \{2, 3, 4, 5\}$**

| lrshape | envIdx | Envelope name | Envelope normalization value for the possible shift values of 0 … 3 | Description |
|---|---|---|---|---|
| 2 | 0 | $Fix-0$ | FESS_inv_sqrt_en [0][0 …3] = $\{1\,485 \cdot 2^{-15}, 1\,548 \cdot 2^{-15}, 1\,620 \cdot 2^{-15}, 1\,704 \cdot 2^{-15}\}$ | Initial bell |
| 3 | 1 | $Fix-I$ | FESS_inv_sqrt_en [1][0 … 3] = $\{980 \cdot 2^{-15}, 1\,031 \cdot 2^{-15}, 1\,620 \cdot 2^{-15}, 1\,704 \cdot 2^{-15}\}$ | LF to HF decaying envelope |
| 4 | 2 | $Fix-II$ | FESS_inv_sqrt_en [2][0 … 3] = $\{1\,417 \cdot 2^{-15}, 1\,450 \cdot 2^{-15}, 1\,485 \cdot 2^{-15}, 1\,548 \cdot 2^{-15}\}$ | Mild centered bell |
| 5 | 3 | $Fix-III$ | FESS_inv_sqrt_en [3][0 … 3] = $\{1\,471 \cdot 2^{-15}, 1\,471 \cdot 2^{-15}, 1\,488 \cdot 2^{-15}, 1\,526 \cdot 2^{-15}\}$ | Delayed bell |

For each of the fixed envelope shapes, twelve (or ten) consecutive signs with a starting point of ***shift*** are encoded consuming 12 (or 10) bits, where a bit set to 1 denotes a negative value in ***y***. For the starting point of the non-zero coefficients, four different shift factor possibilities for the ***shift_idx(==shift)*** value are encoded linearly consuming 2 bits. A total number of $N_{2_5} = (3 \cdot 2^2 \cdot 2^{12} + 1 \cdot 2^2 \cdot 2^{10}) = 49\,152 + 4\,096 = 53\,248$ combinations are used to encode the four fix FESS shapes corresponding to a bit rate of $B_{fixed} = log2(N_{2_5}) = 15{,}58\ bits < 15{,}75$. A shift factor index $\boldsymbol{shift_{idx}}$ of 0 makes the *Ns* consecutive signs start at position 1 out of 0 … 15 , and a shift factor index of 2 makes the Ns consecutive signs start at position 3. The very first leading sign $s_0$ in a FESS pulse sequence is positioned in the 'aux' bit. The remaining envelope Fix-0 values will be multiplexed in a first section $[0 \ldots 8\,192 - 1]$, envelope Fix-1 values will be multiplexed in a second section $[8\,192 \ldots 2 \cdot 8\,192 - 1]$ , envelope Fix-II values are multiplexed in the third segment $[2 \cdot 8\,192 \ldots 3 \cdot 8\,192 - 1]$ , and the information for the fourth envelope, Fix-III is located in the segment $\left[3 \cdot 8\,192 \ldots 53\,248 - 2 - 1\right]$.

For the full and fixed shapes (shapes 1 through 5) a combined 18 bit bitspace is used to index the chosen shape mode among the $N_{1_5} = N_{1,A} + N_{2_5} = 260\,254$ combinations, with a combined multiplexed bit consumption of $B_{1_5} = log2(N_{1_5}) = 17{,}99$ bits.

### 5.3.7.3a.3.5 Low Rate SNS-VQ Stage 2 Shape Search

For the three PVQ pulse configurations ($lrshape \in \{0a, 0b, 1\}$) the same Pyramid VQ shape search is used as in clause 5.3.7.3.3.5, however the DC coefficient is always set to zero for the Low Rate SNS-VQ, and does not need any coding information after the normalized DCT-II transform and thus reducing the maximum Stage 2 dimensionality to M-1=15.

For the FESS configurations the four available fixed envelopes and four possible shifts per envelope are evaluated using a similar unit energy normalized correlation concept as for PVQ, however to limit the dynamic range, the $M-1$ non-energy normalized integer shape candidate $\boldsymbol{y}$ vector coefficents are only allowed to have integer values in the range -12 to 12.

All 16 combinations (4 shifts and 4 FESS-envelopes) are evaluated in the first all positive hyperoctant using maximization of the energy normalized correlation $d_{FESS-shape}$ (where $\boldsymbol{x}$ and $\boldsymbol{y_{envIdx,shift}}$ in the phase search phase starts right after the always zeroed DC coefficient), and then subsequently the *Ns* signs are set based on the sign of the target signal $\boldsymbol{x}$. To limit search complexity, all fixed FESS-shapes have the same gain values, and thus only a single best shape among 16 available FESS envelope and shift configurations is forwarded to the final joint stage 2 shape and gain loop, for determination of the final gain adjusted stage 2 vector.

$$d_{FESS,envIdx,shift} = \boldsymbol{x^T x_q} = \frac{\left(\boldsymbol{x^T} \cdot \boldsymbol{y_{envIdx,shift}}\right)}{\sqrt{\boldsymbol{y_{envIdx,shift}}^T \cdot \boldsymbol{y_{envIdx,shift}}}} \tag{59.16}$$

The FESS shape determination loop for the best envelope and best shift factor is described by the following ANSI -C style pseudo code:

**Table 5.14f: FESS shape search and normalization steps**

| Step | Operations |
|---|---|
| 1 | `/* variable initialization */`<br>`float norm_corr[4][4];`<br>`int16_t best_env_ind=-1;`<br>`int16_t best_shift_ind=-1;`<br>`float best_corr = -1;`<br>`int16_t Ns[4] = {12,12,12,10};`<br>`int16_t *FESS_env = lrsns_fix_env_fx ;` |

| 4 | `FESS_vec[i] with` $i \in [0 \ldots M-1]$<br>is now the vector with the best FESS envelope shape, with unit energy and with a zeroed DC coefficient.<br>The decoder can resynthesize the FESS vector from a received and demultiplexed `best_env_ind`*(==env_idx)*<br>and a demultiplexed and received received `best_shift_ind`, and the received and demultiplexed Ns signs. |

The resulting vector from the FESS shape search above is subsequently closed loop evaluated with a common eight level, three bit adjustment gain table, competing against the other gain-shape vectors related to the shapes 'LR_SplitLF' and 'LR_full', where the 'LF_splitLF' and 'LR_full', have their own individual adjustment gain tables.

#### 5.3.7.3a.3.6 Low Rate SNS-VQ Adjustment Gain Candidates

There are three different adjustment gain candidate sets in the Low Rate SNS. The adjustment gain configuration for each of the low rate shapes are given in Table 5.14g.

**Table 5.14g: LR SNS VQ Second Stage Adjustment Gain sets**

| Gain set index (same as Shape index = $lrshape$) | Corresponding Shape name | Number of gain levels | Adjustment Gain set values ($G_{idxG,\,lrshape}$) See clause 5.9.3b | Start adjustment gain index, $Gminind_{lrshape}$ | End adjustment gain index, $Gmaxind_{lrshape}$ |
|---|---|---|---|---|---|
| 0a/0b | 'LR_splitLF' | 4 (2 bits) | $G_{LRSNS,idxG,0}$ | 0 | 3 |
| 1 | 'LR_full' | 8 (3 bits) | $G_{LRSNS,idxG,1}$ | 0 | 7 |
| 2 | 'LR_fix-0' | 8 (3 bits) | $G_{LRSNS,idxG,2\ldots5}$ (common for all four LR Fix envelopes) | 0 | 7 |
| 3 | 'LR_fix-I' | | | | |
| 4 | 'LR_fix-II' | | | | |
| 5 | 'LR_fix-III' | | | | |

#### 5.3.7.3a.3.7 Low Rate Shape and Gain combination determination

##### 5.3.7.3a.3.7.1 Low Rate Final Stage determination

Even if stage 2 has been applied to reduce the distortion there is still a possibility that the use of stage1 $CB_A$, $CB_B$ or $CB_C$ results in an overall lower distortion. A final stage 1 versus stage 2 (including stage 1 B) MSE evaluation is made before enumerating the stage 2 parameters as follows:

$$\text{stage2use} = \begin{cases} 1 & , \quad if\ dMSE_{ST2} < \left(dMSE_{CB_{A,indA}} \cdot \propto, dMSE_{CB_{B,indB}}, dMSE_{CB_{C,indC}}\right) \\ 0 & , \quad otherwise \end{cases} \tag{59.17}$$

#### 5.3.7.3a.3.8 Low Rate Enumeration of the selected PVQ pulse configurations

The following MPVQ enumeration calls are made for a PVQ based selected *lrshape*.

**Table 5.14h: Low Rate SNS second stage shape enumeration of integer vector $y_{lrshape}$ into MPVQ shape indices *{idxA, idxB}*, and leading signs indices *{LS_indA, LS_indB}* for the PVQ based shapes**

| Shape index (*lrshape* ) | Shape name | Scale factor set A enumeration | Scale factor set B enumeration |
|---|---|---|---|
| 0a | 'LR_splitLF' | *[idxA , LS_indA]* = MPVQenum(*5, $K^A$=6, $y_0$*) | *z(n-10) = $y_0$(n), for n=10…15* *[idxB, LS_indB]* = MPVQenum(8, *2, z*) |
| 0b | | *[idxA , LS_indA]* = MPVQenum(5, *$K^A$=8, $y_0$*) | n/a |
| 1 | 'LR_full' | *[idxA, LS_indA]* = MPVQenum(*15, 5, $y_1$*) | n/a |

#### 5.3.7.3a.3.9 Low Rate Enumeration of the selected FESS pulse configurations

The FESS shapes are enumerated using an envelope value in the range *env_idx* ∈[0 …3], a shift value *shift_idx* ∈ [0…3] and a sequential sign bit sequence for the $N_s$ (12 or 10) signs. The envelope value is indicated by the code space location in the tail section of the stage 2 'LR_full' code space. The 2 bit shift value and the $N_s$ signs are encoded as individual bits in each of those sections. The very first FESS sign $s_0$ is however encoded as the 'aux' value and is thus located in the b0 to b9 code space. The remaining signs $s_{1\ldots(Ns-1)}$ are encoded in sequence with $s_1$ as the most significant bit in a ($N_S$ -1) sized combined codeword. The 2 bit shift codeword is positioned before the combined signs codeword.

### 5.3.7.3a.4 Multiplexing of Low Rate SNS VQ Codewords

An initial segmentation within the first 9 to 10 bits of the Low Rate SNS is used to efficiently convey the stage 1 only operation and to convey the necessary stage 2 gain and shape quantization mode information without adding the complexity of activating the arithmetic range encoder. The result is a variable rate VQ scheme that is using a total bit consumption out of the set 9, 10, 29 and 30 bits. In the majority of encoded audio frames one of the 9 or 10 bit modes will provide sufficient noise shaping quality, while the 29 and 30 bits modes will be in use when a first stage only quantizer is insufficient to produce the desired spectral noise shaping control.

If stage 1 (A, B or C) only ($stage2use == 0$) is selected for transmission, then the variable rate LRSNS-VQ information is multiplexed as follows:

**Table 5.14i: Low Rate SNS Stage 1 only multiplexing in b0 to b9**

| st1Idx | Transmitted value b0 to b8, value range | Transmitted value for stop-bit b9, value range | Total Low Rate SNS bit consumption |
|---|---|---|---|
| 0 ($CB_A$) | $510+indA$, [510 ... 511] | Not available, stop bit not transmitted for $CB_A$ | 9 bits |
| 1 ($CB_B$) | $0+indB$, [0 ... 169] | **1**, [0,1] | 10 bits |
| 2 ($CB_C$) | $170+indC$, [170 ... 339] | **1**, [0,1] | 10 bits |

When the Low Rate SNS stage 2 operation is selected for transmission ($stage2use == 1$), then the variable rate LRSNS-VQ information is multiplexed as:

**Table 5.14j: Low Rate SNS combined Stage 1 B and Stage 2 multiplexing in b0 to b9.**

| st1Idx | st2ShapeIdx | 'aux' bit value | Transmitted value b0 to b8, value range | Transmitted value for "stop" -bit b9, value range | Stage 2 gain bits | Stage 2 shape bits | Total Low Rate SNS bits |
|---|---|---|---|---|---|---|---|
| 1, "$CB_B$" | 1,2,3,4,5 "LR_full"/"LR_fix" | 1 | 340+$indB$, [340 … 509] | **1,** [0,1] | 3 | 18, ($B_{1...5}$ = 17,99) | 30 bits |
| 1, "$CB_B$" | 0, "LR_splitLF" | 0 | 0+$indB$, [0 … 169] | 0, [0,1] | 2 | 18, ($B_0$ = 17,944) | 29 bits |
| 1, "$CB_B$" | 0, "LR_splitLF" | 1 | 170+$indB$, [170 … 339] | 0, [0,1] | 2 | 18, ($B_0$ = 17,944) | 29 bits |
| 1, "$CB_B$" | 1,2,3,4,5 "LR_full"/"LR_fix" | 0 | 340+$indB$, [340 … 509] | **0**, [0,1] | 3 | 18, ($B_{1...5}$ = 17,99 ) | 30 bits |

The '*aux'* bit value in the multiplexing step is set differently by each possible stage 2 mode, for the 'LR_full' mode, the *aux* bit (which can at the receiver side be derived from received bits b0 to b9), is used to transmit the leading sign bit of the MPVQ(N=15, K=5) configuration. For the 'LR_splitLF' mode the *aux* bit is used to transmit the leading sign bit of the MPVQ(N=5, K=6) or MPVQ(N=5, K=8) configurations, and finally for the four "LR_Fix" modes the aux bit is used to transmit the first sign $s_0$ of the encoded *Ns* signs.

Any remaining fractional bits space for the stage 2 shape bits may be used by the decoder to identify bit error conditions, as they are known a priori to not have been sent by the encoder.

High level multiplexing of the "LR_splitLF" mode is shown in the two tables below:

**Table 5.14k: High level multiplexing of the stage 2 'LR_splitLF' shape mode, with *LS_indA* as the *aux* bit**

| Tx value **b0 to b8**, value range | Tx value for "stop"-bit **b9** | **b10 to b11** Stage2 gain bits. value range | **b12 to b21** **(10 bits)** Stage2 ***set A*** shape bits | **b22 to b28** (7 bits) Stage 2 ***set B*** shape bits MPVQ(8,2) including leading sign |
|---|---|---|---|---|
| $[\ indB + LS_indA*N_B\ [$ | 0 | 2 [0 … 3] | **b12 to b21** is idxA from MPVQ(5, 6) [0 … $N_{0,A}/2$[ | **b22** is LS_indB, [0,1] **b23 to b28** is MPVQ_idxB, [0 … $2^6$[ |
| | | | | **or** |
| | | | **b12 to b21** 5 msb's of MPVQ(5,8) idxA in range, [$N_{0,A}/2$ … $N_{0,A}/2 + 2^5$[ | **b22 to b28** 7 lsb's of MPVQ(5,8) idxA in range, [0 … $2^7$[ |

The outline of the multiplexing of the 'LR_full' and 'LR_Fix' shape modes is shown in Table 5.14l:

**Table 5.14l: High Level multiplexing of stage 2 'LRfull' or 'LR_fix', with *LS_indA* or $s_0$ as the *aux* bit**

| Tx value **b0 to b8**, value range | Transmitted value for "stop"-bit **b9** | | **b10 to b12** Stage2 gain bits, value range | **b13 to b29** **(17 bits in total)** Stage2 shape bits | |
|---|---|---|---|---|---|
| | *lrshape* | *parameter* | | Stage 2 shape mode | index range for each *lrshape, ( parameter(s) )* |
| *340+indB, [340 … 509]* | 1 | *LS_indA* | 3, [0 … 7] | 'LRfull' | [ 0 … $N_{0,A}/2$[ , ( *idxA* of MPVQ(15,5) ) |
| | 2 | $s_0$ | | Fix-0 | [ $N_{0,A}/2$ … $N_{0,A}/2$+ (1 << (2+12)) [, (*shift_idx*, *signs_idx*) |
| | 3 | | | Fix-1 | [ $N_{0,A}/2$ + 1·(1 << (2+12)) … $N_{0,A}/2$ + 2·(1 << (2+12))[ |
| | 4 | | | Fix-2 | [ $N_{0,A}/2$ + 2·(1 << (2+12)) … $N_{0,A}/2$ + 3·(1 << (2+12))[ |
| | 5 | | | Fix-3 | [ $N_{0,A}/2$ + 3·(1 << (2+12)) … $N_{(1...5)}$[ |

Detailed multiplexing of the "LR_splitLF", "LR_full" and "LR_fix" mode codewords is described in the side information handling pseudo code of encoder clause 5.3.14.3.3 and decoder clause 5.4.7.2a.

### 5.3.7.3a.5 Synthesis of the Quantized Low Rate SNS scale factor vector

#### 5.3.7.3a.5.1 Low Rate SNS Stage 1 only synthesis

$$scfQ(n) = \begin{cases} st1_{\mathrm{CB_A},indA}(n) & , \quad indA\ for\ CB_A\ was\ transmitted \\ st1_{\mathrm{CB_B},indB}(n) & , \quad indB\ for\ CB_B\ was\ transmitted \\ st1_{\mathrm{CB_C},indC}(n) & , \quad indC\ for\ CB_C\ was\ transmitted \end{cases}, for\ n = 0 \ldots 15 \qquad (59.18)$$

#### 5.3.7.3a.5.2 Low Rate SNS Stage 1 B and Stage 2 synthesis

The DC-removed quantized first stage vector $st1_{CbB,indB,noDC}$, the quantized second stage unit energy shape vector $x_{LRSNS,q,lrshape}$, the quantized adjustment gain $G_{idxG,lrhape}$ (with gain index $idxG$), and the rotation matrix $\boldsymbol{D}$ (used to implement the normalized IDCT-II transform) are used to establish the quantized scale factor vector $scfQ(n)$ as follows:

$$scfQ(n) = st1_{\mathrm{CB_B},indB,noDC}(n) \quad + \quad \mathrm{G}_{LRSNS,idxG,\mathrm{lrshape}} \quad \cdot \sum_{col=0}^{15} \left[ x_{LRSNS,q,\mathrm{lrshape}}(col) \cdot \boldsymbol{D}(col + n \cdot 16\ ) \right] \qquad (59.19)$$
$$, for\ n = 0 \ldots 15$$

### 5.3.7.3a.6 Bit Rate adjustment for Low Rate SNS VQ

In the case stage 1 only is activated the number of bits for the SNS quantizer is set according to:

$$nbits_{SNS} = \begin{cases} 9 & , \quad Stage\ 1\ CB_A\ in\ use \\ 10 & , \quad Stage\ 1\ CB_B\ or\ CB_C\ in\ use \end{cases} \tag{59.20}$$

In the case stage 2 was activated the number of bits for the SNS quantizer is set according to :

$$nbits_{SNS} = \begin{cases} 29 & , \quad Stage\ 2\ in\ the\ 'LR'_{splitLF} mode\ in\ use \\ 30 & , \quad otherwise \end{cases} \tag{59.21}$$

## 5.3.7.4 SNS scale factors interpolation

The quantized scale factors $scfQ(n)$ (obtained in clause 5.3.7.3) are interpolated using:

$$\begin{aligned} scfQint(0) &= scfQ(0) \\ scfQint(1) &= scfQ(0) \\ scfQint(4n+2) &= scfQ(n) + \frac{1}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0..14 \\ scfQint(4n+3) &= scfQ(n) + \frac{3}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0..14 \\ scfQint(4n+4) &= scfQ(n) + \frac{5}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0..14 \\ scfQint(4n+5) &= scfQ(n) + \frac{7}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0..14 \\ scfQint(62) &= scfQ(15) + \frac{1}{8}\big(scfQ(15) - scfQ(14)\big) \\ scfQint(63) &= scfQ(15) + \frac{3}{8}\big(scfQ(15) - scfQ(14)\big) \end{aligned} \tag{60}$$

In case the codec is configured to operate on a number of bands $N_B$ < 64, the number of scale factors need to be reduced using the following pseudo code:

```
if N_B < 32
    n4 = round(abs(1-32/N_B)* N_B)
    n2 = N_B - n4

    for i=0..n4-1
        tmp(i) = 1/4 Σ_{n=4i}^{n=4i+3} scfQint(n)

    for i=0..n2-1
        tmp(n4+i) = 1/2 Σ_{n=4n4+2i}^{n=4n4+2i+1} scfQint(n)

else if N_B < 64
    n2 = 64 -N_B;

    for i=0..n2-1
        tmp(i) = 1/2 Σ_{n=2i}^{n=2i+1} scfQint(n)
    for i=n2.. N_B-1
        tmp(i) = scfQint(n2 + i)
```

In case $N_B$ < 64, the vector tmp is copied to $scfQint$. Finally, the scale factors are transformed back into the linear domain using:

$$g_{SNS}(b) = 2^{-scfQint(b)} \quad for\ b = 0 \ldots N_B \tag{61}$$

### 5.3.7.5 Spectral shaping

The SNS scale factors $g_{SNS}(b)$ are applied on the MDCT frequency coefficients for each band separately in order to generate the shaped spectrum $X_s(k)$ as outlined by the following code:

```
for b=0 to N_b − 1 do
    for k=I_fs(b) to I_fs(b + 1) − 1
        X_s(k) = X(k) · g_SNS(b)
```

## 5.3.8 Bandwidth control

For specific scenarios a bandwidth restricted LC3plus frame might be required. The bandwidth is controlled by the parameter $B_c$ representing the audio bandwidth in Hz. Depending on $B_c$, the start frequency index $B_i$ is calculated by $B_i = \left\lfloor B_c \cdot \frac{N_{ms}}{500} \right\rfloor$. A short roll-off is applied on the shaped MDCT spectrum and the remaining lines are set to zero.

$$\begin{aligned} X_s(B_i + k) &\leftarrow X_s(B_i + k) \cdot 2^{-(k+2)} \quad for\ k = -1 \ldots 2 \\ X_s(B_i + k) &= 0 \quad for\ k = 3 \ldots N_E \end{aligned} \tag{62}$$

## 5.3.9 Temporal Noise Shaping (TNS)

### 5.3.9.1 Overview

Temporal Noise Shaping (TNS) is used to control the temporal shape of the quantization noise within each window of the transform. If TNS is active in the current frame, up to two filters per MDCT-spectrum will be applied. The processing steps are outlined in Figure 5.6.

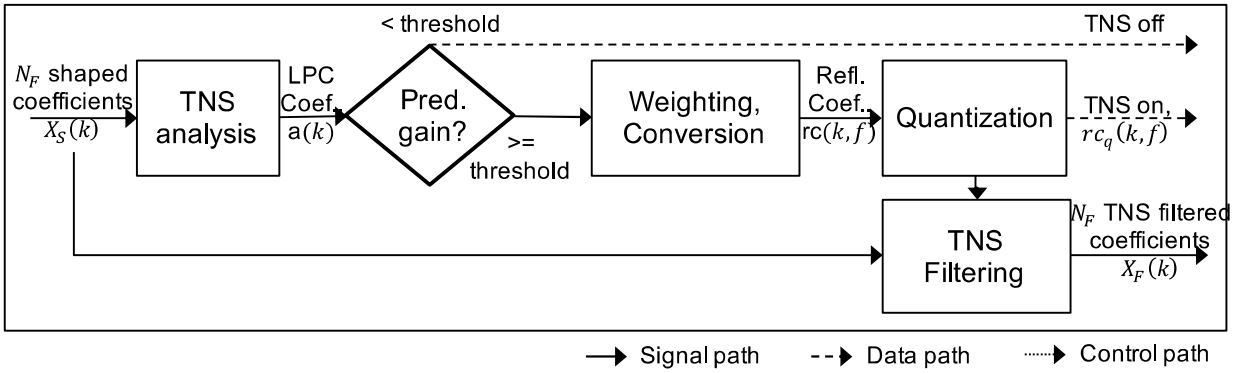

**Figure 5.6: TNS encoder overview**

The number of filters for each configuration and the start and the stop frequency of each filter are given in Table 5.15.

**Table 5.15: TNS encoder parameters**

| $N_{ms}$ | Bandwidth | num_tns_filters | start_freq(f) | stop_freq(f) | sub_start(f,s) | sub_stop(f,s) |
|---|---|---|---|---|---|---|
| 2,5 | NB | 1 | {3} | {20} | {{3, 10}} | {{10, 20}} |

| 10 | FB | 2 | {12, 200} | {200, 400} | {{12, 74, 137}, {200, 266, 333}} | {{74, 137, 200}, {266, 333, 400}} |

The TNS encoding steps are described in the clauses below. First, an analysis estimates a set of reflection coefficients for each TNS Filter. Then, these reflection coefficients are quantized. And finally, the MDCT-spectrum is filtered using the quantized reflection coefficients.

For $N_{ms}$ = 1,25 ms, TNS is disabled by setting *num_tns_filters* always to zero.

### 5.3.9.2 TNS analysis

The complete TNS analysis described below is repeated for every TNS filter $f$, with $f = 0 \ldots \text{num_tns_filters-1}$ ($n$um_filters is given in Table 5.15).

The normalized autocorrelation function is calculated as follows, for each $k = 0 \ldots 8$:

$$r(k) = \begin{cases} r_0(k) & \text{, if } \prod_{s=0}^{2} e(s) = 0 \\ \sum_{s=0}^{2} \frac{\sum_{n=\text{sub_start}(f,s)}^{\text{sub_stop(f,s)-1-k}} X_s(n) X_s(n+k)}{e(s)} & \text{, otherwise} \end{cases} \quad (63)$$

where:

$$r_0(k) = \begin{cases} 3 & , if\ k = 0 \\ 0 & , otherwise \end{cases} \quad (64)$$

and

$$e(s) = \sum_{n=\text{sub_start}(f,s)}^{\text{sub_stop(f,s)-1}} X_s(n)^2 \quad for\ s = 0 \ldots 2 \quad (65)$$

where $\text{sub_start}(f, s)$ and $\text{sub_stop}(f, s)$ are given in Table 5.15.

The normalized autocorrelation function is lag-windowed using:

$$r_w(k) = r(k) \exp\left[-\frac{1}{2}(0{,}02\pi k)^2\right] \quad for\ k = 0 \ldots 8 \quad (66)$$

The Levinson-Durbin recursion is used to obtain LPC coefficients $a(k), k = 0 \ldots 8$ and a prediction error $e$. It is described by the following pseudo code:

$e = r_w(0)$
$a^0(0) = 1$
for $k = 1$ to $8$ do
    $rc = \frac{-\sum_{n=0}^{k-1} a^{k-1}(n) r_w(k-n)}{e}$
    $a^k(0) = 1$
    for $n = 1$ to $k - 1$ do
        $a^k(n) = a^{k-1}(n) + rc \cdot a^{k-1}(k-n)$
    $a^k(k) = rc$
    $e = (1 - rc^2) \cdot e$

where $a(k) = a^8(k), k = 0 \ldots 8$ are the estimated LPC coefficients and $e$ is the prediction error.

The decision to turn the TNS filter $f$ on or off in the current frame is based on the prediction gain and the *near_nyquist_flag*.

If predGain $> thresh$ and the *near_nyquist_flag* obtained in clause 5.3.4a is 0, then turn on the TNS filter $f$ with $thresh = 1{,}5$ and the prediction gain is computed by:

$$\text{predGain} = \frac{r_w(0)}{e} \tag{67}$$

The additional steps described below are performed only if the TNS filter $f$ is turned on.

A weighting factor is computed by:

$$\gamma = \begin{cases} 1 - (1 - \gamma_{min})\dfrac{thresh2 - \text{predGain}}{thresh2 - thresh} & \text{, if tns_lpc_weighting} = 1 \text{ and predGain} < thresh2 \\ 1 & \text{, otherwise} \end{cases} \tag{68}$$

where $thresh2 = 2$, $\gamma_{min} = 0{,}85$, and

$$\text{tns_lpc_weighting} = \begin{cases} 1 & \text{, if nbits} < 480 \\ 0 & \text{, otherwise} \end{cases} \tag{69}$$

The LPC coefficients are weighted using the factor $\gamma$:

$$a_w(k) = \gamma^k a(k) \quad for \;\; k = 0 \ldots 8 \tag{70}$$

The weighted LPC coefficients are converted to reflection coefficients using the following algorithm:

$a^K(k) = a_w(k), k = 0, \ldots, 8$
`for` $k = 8$ `to` $1$ `do`
    $rc(k-1) = a^k(k)$
    $e = (1 - rc(k-1)^2)$
    `for` $n = 1$ `to` $k - 1$ `do`
        $a^{k-1}(n) = \frac{a^k(n) - rc(k-1)a^k(k-n)}{e}$

where $rc(k, f) = rc(k), k = 0 \ldots 7$ are the final estimated reflection coefficients for the TNS filter $f$.

If the TNS filter $f$ is turned off, then the reflection coefficients are simply set to 0: $rc(k, f) = 0, \;\; k = 0 \ldots 7$.

### 5.3.9.3 Quantization

For each TNS filter $f$, the reflection coefficients obtained in clause 5.3.9.2 are quantized using scalar uniform quantization in the arcsine domain:

$$rc_i(k, f) = \text{nint}\left[\frac{\arcsin\big(rc(k, f)\big)}{\Delta}\right] + 8 \quad for \;\; k = 0 \ldots 7 \tag{71}$$

and

$$rc_q(k, f) = \frac{\text{nint}[2^{15} \cdot \sin[\Delta(rc_i(k, f) - 8)]]}{2^{15}} \;\; for \;\; k = 0 \ldots 7 \tag{72}$$

where $\Delta = \frac{\pi}{17}$ and $\text{nint}(.)$ is the rounding-to-nearest-integer function.
$rc_i(k, f)$ are the quantizer output indices and $rc_q(k, f)$ are the quantized reflection coefficients rounded to a 16-bit precision to unify representation on various platforms.

The order of the quantized reflection coefficients is calculated using:

$k = 7$
`while` $k \geq 0$ `and` $rc_q(k, f) = 0$ `do`
    $k = k - 1$
$rc_{order}(f) = k + 1$

The total number of bits consumed by TNS in the current frame can then be computed as follows:

$$nbits_{TNS} = \sum_{f=0}^{\text{num_tns_filters}-1} \left\lceil \frac{2\,048 + nbits_{TNS_{order}}(f) + nbits_{TNS_{coef}}(f)}{2\,048} \right\rceil \quad (73)$$

with:

$$nbits_{TNS_{order}}(f) = \begin{cases} \text{ac_tns_order_bits[tns_lpc_weighting]}[rc_{order}(f)-1] & ,if\ rc_{order}(f) > 0 \\ 0 & ,otherwise \end{cases} \quad (74)$$

and

$$nbits_{TNS_{coef}}(f) = \begin{cases} \sum_{k=0}^{rc_{order}(f)-1} \text{ac_tns_coef_bits}[k][rc_i(k,f)] & ,if\ rc_{order}(f) > 0 \\ 0 & ,otherwise \end{cases} \quad (75)$$

The tables ac_tns_order_bits and ac_tns_coef_bits are given in clause 5.9.4.

### 5.3.9.4 Filtering

The MDCT spectrum $X_s(n)$ is filtered using the following algorithm:

```
for k = 0 to (N_E − 1) do
    X_f(k) = X_s(k)

st^0 = st^1 = ··· = st^7 = 0
for f = 0 to num_tns_filters-1 do
    if (rc_order(f) > 0)
        for n = start_freq(f) to stop_freq(f) − 1 do
            t = X_s(n)
            st^save = t
            for k = 0 to (rc_order(f) − 1) do
                St^tmp = rc_q(k,f) · t + st^k
                t = t + rc_q(k,f) st^k
                st^k = st^save
                St^save = st^tmp
            X_f(n) = t^8(n)
```

where $X_f(n)$ is the TNS filtered MDCT spectrum. The initial condition for $s^k(n-1)$ for the first TNS filter *(f = 0)* is 0, for the second TNS filter *(f = 1)* is carried over from the first TNS filter *(f = 0)*.

## 5.3.10 Long Term Post Filter (LTPF)

### 5.3.10.1 Overview

A Long Term Post Filter (LTPF) module controls a pitch based postfilter on the decoder side which perceptually shapes quantization noise in spectral valleys. Figure 5.7 outlines the processing steps of the LTPF encoder.

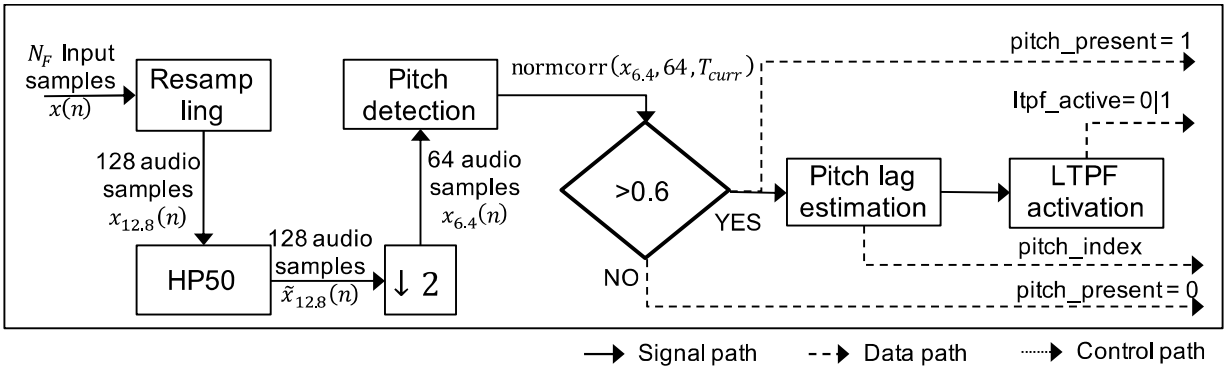

**Figure 5.7: LTPF encoder overview**

NOTE: The processing of the LTPF decoder (clause 5.4.9) depends on the bitrate of the current frame. At high bitrates (see clause 5.4.9.3 for exact parameters), the coefficients $c_{num}$ and $c_{den}$ are set to zero, meaning that the transition handling (clause 5.4.9.2) has no effect on the input data. However, the pitch information computed in clause 5.3.10.7 is very valuable for a packet loss concealment algorithm and is therefore calculated and encoded into the bitstream on the encoder side regardless of the bitrate of the current frame.

### 5.3.10.2 Time-domain signals

Several time-domain signals are computed in the LTPF encoder described below. These are processed with filters which contain a memory and thus operate on audio samples computed in the previous frames. For simplicity, audio samples of past frames are accessed by negative indexing, e.g. $x_s(-1)$ is the most recent sample of the signal $x_s$ in the previous frame. Note that in practice, a buffer mechanism would have to be implemented.

### 5.3.10.3 Resampling

The input signal at sampling rate $f_s$ is resampled at a fixed sampling rate of 12,8 kHz (for input sampling rates of 8, 16, 24, 32 and 48 kHz and to about 11,76 kHz for input sampling rate of 44,1 kHz). The resampling is performed using an upsampling step followed by a low-pass-filtering step followed by a downsampling step approach that can be formulated as a polyphase implementation as follows:

$$x_{12,8}(n) = res_{fac} \cdot P \sum_{k=-\frac{120}{P}}^{\frac{120}{P}} x_s\left(\left\lfloor\frac{15n}{P}\right\rfloor + k - \frac{120}{P}\right) h_{12,8}\left(P \cdot k - 15 \cdot n \ \cdot (\mathrm{mod}\ P)\right) \quad for \quad n = 0 \ldots len_{12,8} - 1 \tag{76}$$

where $x_s(n)$ is the scaled input signal, $x_{12,8}(n)$ is the resampled signal at 12,8 kHz, $P = \frac{192\,kHz}{f_s}$ is the upsampling factor (note that $P = 4$ for $f_s = 44{,}1\ kHz$) and $h_{12,8}$ is the impulse response of a FIR low-pass filter given by:

$$h_{12,8}(n) = \begin{cases} \text{tab_resamp_filter}[n + 119] & \text{, if } -120 < n < 120 \\ 0 & \text{, otherwise} \end{cases} \tag{77}$$

with the table tab_resamp_filter values are given in clause 5.9.5 and the length of the resampled signal defined as:

$$len_{12,8} = \frac{N_{ms} \cdot 128}{10} \tag{77.1}$$

and

$$res_{fac} = \begin{cases} 0{,}5, & if\ f_s == 8\ kHz \\ 1, & otherwise \end{cases} \tag{77.2}$$

### 5.3.10.4 High-pass filtering

The resampled signal is high-pass filtered using a 2-order IIR filter with a cut-off frequency of 50 Hz and a transfer function given by:

$$H_{50}(z) = \frac{0{,}9827947082978771 - 1{,}965589416595754 z^{-1} + 0{,}9827947082978771 z^{-2}}{1 - 1{,}9652933726226904 z^{-1} + 0{,}9658854605688177 z^{-2}} \tag{78}$$

The high-pass filtered signal is denoted as $\tilde{x}_{12,8}(n)$ in the following. The high-pass filtered signal is further delayed by 24 samples:

$$\tilde{x}_{12,8_D}(n) = \tilde{x}_{12,8}(n - D_{LTPF}) \quad for\ \ n = 0 \ldots len_{12,8} + 1 \tag{79}$$

where a negative index of $\tilde{x}_{12,8}$ means that the sample has been taken from the previous processed frame. At start-up, these values are considered to be zero (the last $D_{LTPF}$ values of the previously processed frame). $D_{LTPF}$ = 44 samples for $N_{ms}$ = 7,5 ms, $D_{LTPF}$ = 8 samples for $N_{ms}$ = 1,25 ms, otherwise $D_{LTPF}$ = 24.

### 5.3.10.5 Pitch detection algorithm

The delayed 12,8 kHz signal $\tilde{x}_{12,8_D}(n)$ is downsampled by a factor of 2 to 6,4 kHz using:

$$x_{6,4}(n) = \sum_{k=0}^{4} \tilde{x}_{12,8_D}(2n + k - 3)h_2(k) \quad for \;\; n = 0 \ldots len_{6,4} - 1 \tag{80}$$

where:

$$len_{6,4} = \frac{len_{12,8}}{2} \tag{80.1}$$

with the FIR filter coefficients given by:

```
h2[5] = {
0,1236796411180537, 0,2353512128364889, 0,2819382920909148, 0,2353512128364889, 0,1236796411180537}
```

The autocorrelation of $x_{6.4}(n)$ is computed by:

$$R_{6,4}(k) = \sum_{n=\Delta_{6,4}}^{len_{6,4}-1} x_{6,4}(n)x_{6,4}(n-k) \quad for \;\; k = k_{min} \ldots k_{max} \tag{81}$$

where $k_{min} = 17$ and $k_{max} = 114$ as the minimum and maximum lags and $\Delta_{6,4} = -56$ for $\mathrm{N_{ms}} = 1{,}25$, $\Delta_{6,4} = -48$ for $\mathrm{N_{ms}} = 2{,}5$, $\Delta_{6,4} = -32$ for $\mathrm{N_{ms}} = 5$ and $\Delta_{6,4} = 0$ for $\mathrm{N_{ms}} > 5$. A negative index of $x_{6,4}$ means that the sample has been taken from the previous processed frame. At start-up, these values shall be set to zero.

The autocorrelation is weighted using:

$$R^{w}_{6,4}(k) = R_{6,4}(k)w(k) \quad for \;\; k = k_{min} \ldots k_{max} \tag{82}$$

where $w(k)$ is defined as follows:

$$w(k) = 1 - 0{,}5\frac{(k - k_{min})}{(k_{max} - k_{min})} \quad for \;\; k = k_{min} \ldots k_{max} \tag{83}$$

The first estimate of the pitch-lag $T_1$ is the lag that maximizes the weighted autocorrelation:

$$T_1 = \underset{k=k_{min} \ldots k_{max}}{\operatorname{argmax}} \; R^{w}_{6,4}(k) \tag{84}$$

The second estimate of the pitch-lag $T_2$ is the lag that maximizes the non-weighted autocorrelation in the neighborhood of the pitch-lag estimated in the previous frame:

$$T_2 = \underset{k=k'_{min} \ldots k'_{max}}{\operatorname{argmax}} \; R_{6,4}(k) \tag{85}$$

with $k'_{min} = \max\left(k_{min}, T_{prev} - 4\right)$, $k'_{max} = \min\left(k_{max}, T_{prev} + 4\right)$ and $T_{prev}$ is the final pitch-lag estimated in the previous frame for $\mathrm{N_{ms}} > 5$ ($T_{prev} = k_{min}$ in the first frame). For $\mathrm{N_{ms}} = 5$, $T_{prev}$ is the final pitch-lag estimated in the frame preceding the previous frame, i.e, $T_{prev}$ is updated every second frame. For $\mathrm{N_{ms}} = 2{,}5$, $T_{prev}$ is the final pitch-lag estimated three frames prior, i.e $T_{prev}$ is updated every fourth frame. For $\mathrm{N_{ms}} = 1{,}25$, $T_{prev}$ is the final pitch-lag estimated seven frames prior, i.e. $T_{prev}$ is updated every eight frame. Note that if more than one lag maximizes the (non-weighted) autocorrelation, the smallest lag is chosen.

The final estimate of the pitch-lag in the current frame is then given by:

$$T_{curr} = \begin{cases} T_1 & \text{if normcorr}\left(x_{6,4}, corr_{len}, T_2\right) \leq 0{,}85 \cdot \text{normcorr}\left(x_{6,4}, corr_{len}, T_1\right) \\ T_2 & \text{otherwise} \end{cases} \quad (86)$$

where $\text{normcorr}(x, L, T)$ is the normalized correlation of the signal $x$ of length $L$ at lag $T$:

$$\text{normcorr}(x, L, T) = \max\left(0, \frac{\sum_{n=\Delta_{6,4}}^{L-1} x(n)x(n-T)}{\sqrt{\sum_{n=\Delta_{6,4}}^{L-1} x^2(n) \sum_{n=\Delta_{6,4}}^{L-1} x^2(n-T)}}\right) \quad (87)$$

and

$$corr_{len} = \begin{cases} 64, & N_{ms} = 10 \\ 48, & N_{ms} = 7{,}5 \\ 64, & N_{ms} = 5 \\ 64, & N_{ms} = 2{,}5 \end{cases} \quad (87.1)$$

A negative index of x means that the sample has been taken from the previous processed frame. At start-up, these values shall be set to zero.

### 5.3.10.6 LTPF bitstream

The first bit of the LTPF bitstream signals the presence of the pitch-lag parameter in the bitstream. It is obtained by:

$$\text{pitch_present} = \begin{cases} 1 & \text{if normcorr}\left(x_{6,4}, corr_{len}, T_{curr}\right) > 0{,}6 \\ 0 & \text{otherwise} \end{cases} \quad (88)$$

If pitch_present is 0, no more bits are encoded, resulting in a LTPF bitstream of only one bit.

If pitch_present is 1, two more parameters are encoded, one pitch-lag parameter encoded in 9 bits, and one bit to signal the activation of LTPF. In that case, the LTPF bitstream is composed by 11 bits.

$$nbits_{LTPF} = \begin{cases} 1 & , if \text{ pitch_present} = 0 \\ 11 & , otherwise \end{cases} \quad (89)$$

The pitch-lag parameter and the activation bit are obtained as described in the following clauses.

For $\text{N}_{\text{ms}} = 1{,}25$, the LTPF data is split over two subsequent frames. The transmission status is controlled by the variable $TX_{LTPF}$ which shall be initialized to 0. For this mode, the LTPF bitstream is composed by 2, 6 or 7 bits.

$$nbits_{LTPF} = \begin{cases} 2 & , if \text{ pitch_present} = 0 \\ 6 & , if \text{ pitch_present} = 1 \text{ AND ltpf_active=1 AND } TX_{LTPF} = 0 \\ 7 & , otherwise \end{cases} \quad (89.1)$$

### 5.3.10.7 LTPF pitch-lag parameter

The integer part of the LTPF pitch-lag parameter is given by:

$$\text{pitch_int} = \underset{k=k''_{min} \ldots k''_{max}}{\text{argmax}} R_{12,8}(k) \quad (90)$$

with:

$$R_{12,8}(k) = \frac{\sum_{n=\Delta_{12,8}}^{len_{12,8}-1} \tilde{x}_{12,8_D}(n)\tilde{x}_{12,8_D}(n-k)}{\sqrt{\sum_{n=\Delta_{12,8}}^{len_{12,8}-1} \tilde{x}^2_{12.8_D}(n) \sum_{n=\Delta_{12,8}}^{len_{12,8}-1} \tilde{x}^2_{12,8_D}(n-k)}} \; for\; k = (k''_{min} - 4) \ldots (k''_{max} + 4) \quad (91)$$

and $k''_{min} = \max(32, 2T_{curr} - 4)$, $k''_{max} = \min(228, 2T_{curr} + 4)$ and $\Delta_{12,8} = -112$ for $\text{N}_{\text{ms}} = 1{,}25$, $\Delta_{12,8} = -96$ for $\text{N}_{\text{ms}} = 2{,}5$, $\Delta_{12,8} = -64$ for $\text{N}_{\text{ms}} = 5$ and $\Delta_{12,8} = 0$ for $\text{N}_{\text{ms}} > 5$.

A negative index of $\tilde{x}_{12,8_D}$ means that the sample has been taken from the previous processed frame. At start-up, these values shall be set to zero.

The fractional part of the LTPF pitch-lag is then given by:

$$\text{pitch_fr} = \begin{cases} 0 & \text{if pitch_int} \geq 157 \\ \underset{d=-2,0,2}{\operatorname{argmax}}\, interp(d) & \text{if } 157 > \text{pitch_int} \geq 127 \\ \underset{d=-3\ldots3}{\operatorname{argmax}}\, interp(d) & \text{if } 127 > \text{pitch_int} > 32 \\ \underset{d=0\ldots3}{\operatorname{argmax}}\, interp(d) & \text{if pitch_int} = 32 \end{cases} \tag{92}$$

with:

$$interp(d) = \sum_{m=-4}^{4} R_{12,8}(\text{pitch_int} + m) h_4(4m - d), \tag{93}$$

$d$ being an array of pre-defined indices dependent on pitch_int and $h_4$ is the impulse response of a FIR low-pass filter given by:

$$h_4(n) = \begin{cases} \text{tab_ltpf_interp_R}(n + 15) & \text{, if } -16 < n < 16 \\ 0 & \text{, otherwise} \end{cases} \tag{94}$$

with tab_ltpf_interp_R as provided by Table 5.42 in clause 5.9.5. However, if pitch_int $= k''_{min}$, then $d$ in equation (92) is starting from 0.

If pitch_fr $< 0$ then both pitch_int and pitch_fr are modified according to:

$$\begin{aligned} \text{pitch_int} &= \text{pitch_int} - 1 \\ \text{pitch_fr} &= \text{pitch_fr} + 4 \end{aligned} \tag{95}$$

Finally, the pitch-lag parameter index is given by:

$$\text{pitch_index} = \begin{cases} \text{pitch_int} + 283 & \text{if pitch_int} \geq 157 \\ 2 \cdot \text{pitch_int} + \dfrac{\text{pitch_fr}}{2} + 126 & \text{if } 157 > \text{pitch_int} \geq 127 \\ 4 \cdot \text{pitch_int} + \text{pitch_fr} - 128 & \text{if } 127 > \text{pitch_int} \end{cases} \tag{96}$$

### 5.3.10.8 LTPF activation bit

A normalized correlation is first computed as follows:

$$nc = \frac{\sum_{n=\Delta_{12,8}}^{len_{12,8}-1} x_i(n, 0) x_i(n - \text{pitch_int}, -\text{pitch_fr})}{\sqrt{\sum_{n=\Delta_{12,8}}^{len_{12,8}-1} {x_i}^2(n, 0) \sum_{n=\Delta_{12,8}}^{len_{12,8}-1} {x_i}^2(n - \text{pitch_int}, -\text{pitch_fr})}} \tag{97}$$

with:

$$x_i(n, d) = \sum_{k=-2}^{2} \tilde{x}_{12,8_D}(n + k) h_i(4k - d) \tag{98}$$

and $h_i$ is the impulse response of a FIR low-pass filter given by:

$$h_i(n) = \begin{cases} \text{tab_ltpf_interp_x12k8}(n + 7) & \text{, if } -8 < n < 8 \\ 0 & \text{, otherwise} \end{cases} \tag{99}$$

with tab_ltpf_interp_x12k8 as given in clause 5.9.5.

The LTPF activation bit is then set according to:

```
if (gain_ltpf)
{
   activation_due_to_past_corr = mem_nc[1] > 0.94;
   activation_due_to_stable_pitch = 1;
   if (N_ms = 1.25) {
      activation_due_to_past_corr &= (mem_nc[2] > 0.94);
      activation_due_to_past_corr &= (mem_nc[3] > 0.94);
       activation_due_to_past_corr &= (mem_nc[4] > 0.94);
       activation_due_to_stable_pitch =  max(pitch, mem_pitch)*0.7f < min(pitch, mem_pitch);
    }
       activation = activation_due_to_past_corr && activation_due_to_stable_pitch;
   if (
       (mem_ltpf_active==0 && (N_ms == 10 || activation) && mem_nc[0]>0.94 && nc>0.94) ||
       (mem_ltpf_active==1 && nc>0.9) ||
       (mem_ltpf_active==1 && abs(pitch-mem_pitch)<2 && (nc-mem_nc[0])>-0.1 && nc>0.84)
      )
   {
       ltpf_active = 1;
   }
   else
   {
       ltpf_active = 0;
   }
} else
{
    ltpf_active = 0;
}
```

where mem_ltpf_active is the value of ltpf_active in the previous frame (it is 0 if pitch_present = 0 in the previous frame), mem_nc[x] is the value of nc in the (x-1)$^{th}$ previous frame (it is 0 if pitch_present = 0 in the previous frame), pitch = pitch_int+pitch_fr/4, mem_pitch is the value of pitch in the previous frame (it is 0 if pitch_present == 0 in the previous frame) and gain_ltpf is a global parameter of the LTPF obtained in clause 5.4.9.3.

The LTPF shall be disabled for signals with a comparatively high energy in the range close to the Nyquist frequency; therefore, the value of ltpf_active is set to 0 if the near_nyquist_flag in clause 5.3.4a is 1.

## 5.3.11 Spectral quantization

### 5.3.11.1 Overview

The MDCT spectrum after TNS filtering ($X_f(n)$, see clause 5.3.9.4) is quantized using dead-zone plus uniform threshold scalar quantization and the quantized MDCT spectrum $X_q(n)$ is then encoded using arithmetic encoding. A global gain $gg$ controls the step size of the quantizer. This global gain is quantized with 8 bits and the quantized global gain index $gg_{ind}$ is then an integer between 0 and 255. The global gain index is chosen such that the number of bits needed to encode the quantized MDCT spectrum is as close as possible to the available bit budget.

### 5.3.11.2 Bit budget

The number of bits available for coding the spectrum is given by:

$$nbits_{spec} = nbits - nbits_{bw} - nbits_{TNS} - nbits_{LTPF} - nbits_{SNS} - nbits_{gain} - nbits_{nf} - nbits_{ari} \quad (100)$$

with $nbits$ given in clause 5.2.5, $nbits_{bw}$ given in clause 5.3.5, $nbits_{TNS}$ given in clause 5.3.9.3, $nbits_{LTPF}$ given in clause 5.3.10.6, $nbits_{SNS} = 38$, $nbits_{gain} = 8$, $nbits_{nf} = 3$, and

$$nbits_{ari} = \begin{cases} \left\lceil \log_2\left(\frac{N_E}{2}\right) \right\rceil + 3 & \text{, if } nbits \leq 1\,280 \\ \left\lceil \log_2\left(\frac{N_E}{2}\right) \right\rceil + 4 & \text{, if } 1\,280 < nbits \leq 2\,560 \\ \left\lceil \log_2\left(\frac{N_E}{2}\right) \right\rceil + 5 & \text{, otherwise} \end{cases} \quad (101)$$

### 5.3.11.3 First global gain estimation

An offset is first computed using:

$$nbits_{offset} = \begin{cases} 0{,}8 \cdot nbits_{offset}^{old} + 0{,}2 \cdot \min\left(40, \max\left(-40, nbits_{offset}^{old} + nbits_{spec}^{old} - nbits_{est}^{old}\right)\right) & \text{, if } reset_{offset}^{old} = 0 \\ 0 & \text{, otherwise} \end{cases} \quad (102)$$

with $nbits_{offset}^{old}$ is the value of $nbits_{offset}$ in the previous frame, $nbits_{spec}^{old}$ is the value of $nbits_{spec}$ in the previous frame, $nbits_{est}^{old}$ is the value of $nbits_{est}$ in the previous frame ($nbits_{est}$ is computed in clause 5.3.11.5) and $reset_{offset}^{old}$ is the value of $reset_{offset}$ in the previous frame ($reset_{offset}$ is computed at the end of this clause). Note that $nbits_{offset}^{old}, nbits_{spec}^{old}, nbits_{est}^{old}$ and $reset_{offset}^{old}$ are all initialized to zero before the first frame is processed. If the spectrum was re-quantized in the previous frame, $nbits_{offset}^{old}, nbits_{spec}^{old}\ and\ reset_{offset}^{old}$ refer to the values prior to re-quantization.

This offset is then used to adjust the number of bits available for coding the spectrum:

$$nbits'_{spec} = \text{nint}\left(nbits_{spec} + nbits_{offset}\right) \quad (103)$$

A global gain index is then estimated such that the number of bits needed to encode the quantized MDCT spectrum is as close as possible to the available bit budget. This estimation is based on a low-complexity bisection search which coarsely approximates the number of bits needed to encode the quantized spectrum.

For $\mathrm{N_{ms}} = 1{,}25$ the initial number of gain estimation analysis blocks for FB ( $f_s = 48\,000$) , $\frac{N_E}{3}$ may become a fractional number. To handle this, the number of analysis blocks are extended by setting $N_{E,orig} = N_E$ and then temporarily setting $N_E = 3 \cdot \left\lceil \frac{N_{E,orig}}{3{,}0} \right\rceil$, and extend the spectrum $X_f$ by zeroed coefficients $X_f(n), n \in [N_{E,orig} \quad \ldots \quad (N_E - 1)]$.

For $\mathrm{N_{ms}} = 1{,}25$ the number of estimation blocks may become too low for a high precision global gain estimation, the block size is therefore conditionally adjusted to be two or three coefficients wide. The block width $N_c$ and the related in-loop scaling factor $\gamma_c$ are set according to:

$$N_c = \begin{cases} 2 & , \quad N_{ms} = 1{,}25\ and\ N_{E,orig} \leq 40 \\ 3 & , \quad N_{ms} = 1{,}25\ and\ N_{E,orig} \geq 50 \\ 4 & , \quad otherwise \end{cases} \quad (103.1)$$

$$\gamma_c = \frac{\mathrm{N_c}}{4} \quad (103.2)$$

The low complex estimation algorithm can then be described as follows:

Compute the quantized gain index offset $gg_{off}$ by:

$$gg_{off} = -\min\left(115, \left\lfloor \frac{nbits}{10 \cdot (f_s^{ind} + 1)} \right\rfloor\right) - 105 - 5 \cdot (f_s^{ind} + 1) \quad (104)$$

For $\mathrm{N_{ms}} = 1{,}25$ a different tilt and offset limit is used as follows:

$$gg_{off,tmp} = -\left(\min\left(115, \left\lfloor nbits \cdot \gamma_{off,1.25}[f_s^{ind}] \right\rfloor\right) + (105 + 5 \cdot (f_s^{ind} + 1))\right) \quad (104.1)$$

$$gg_{off,1,25} = \begin{cases} \max\left(-135, gg_{off,tmp}\right) & , f_s^{ind} \leq 1 \\ gg_{off,tmp} & \text{, otherwise} \end{cases} \quad (104.2)$$

, where the tilt control vector $\gamma_{off,1,25}$ is given by:

$$\gamma_{off,1.25}[f_s^{ind}] = \{\, 20\,480, 17\,408, 17\,476, 13\,107, 10\,486, 8\,738, 7\,490 \,\} \cdot 2^{-19}\ , \qquad f_s^{ind} \in [0 \ldots 5] \quad (104.3)$$

and the energy E[k] (in dB) of blocks of $N_c$ MDCT coefficients given by:

$$E(k) = 10 \cdot \log_{10}\left(2^{-31} + \sum_{n=0}^{N_c-1} X_f(N_c \cdot k + n)^2\right) \quad for \quad k = 0 \ldots \frac{N_E}{N_c} - 1 \tag{105}$$

and conduct the following steps:

```
fac = 256;
gg_ind = 255;
for (iter = 0; iter < 8; iter++)
{
    fac >>= 1;
    gg_ind -= fac;
    tmp = 0;
    iszero = 1;
    for (i = N_E/N_c-1; i >= 0; i--)
    {
        if (E[i]*28/20 < (gg_ind+gg_off))
        {
            if (iszero == 0)
            {
                tmp += γ_c*2.7*28/20;
            }
        }
        else
        {
            if ((gg_ind+gg_off) < E[i]*28/20 – γ_c*43*28/20)
            {
                tmp += 2*E[i]*28/20 – 2*(gg_ind+gg_off) – γ_c*36*28/20;
            }
            else
            {
                tmp += E[i]*28/20 – (gg_ind+gg_off) + γ_c*7*28/20;
            }
            iszero = 0;
        }
    }
    if (tmp > nbits'_spec*1.4*28/20 && iszero == 0)
    {
        gg_ind += fac;
    }
}
```

Finally, the quantized gain index is limited such that the quantized spectrum stays within the range [-32 767, 32 767]:

```
if (gg_ind < gg_min || X_f^max == 0)
{
    gg_ind = gg_min;
    reset_offset = 1;
}
else
{
    reset_offset = 0;
}
```

with:

$$gg_{min} = \begin{cases} \left\lceil 28 \cdot \log 10\left(\frac{X_f^{max}}{32\,767 - 0{,}375}\right)\right\rceil - gg_{off} & \text{, if } X_f^{max} > 0 \\ 0 & \text{, otherwise} \end{cases} \tag{106}$$

and

$$X_f^{max} = \max_{0 \le n < N_E} \left|X_f(n)\right| \tag{107}$$

### 5.3.11.4 Quantization

The quantized global gain index found in clause 5.3.11.3 is first unquantized using:

$$gg = 10^{\frac{gg_{ind}+gg_{off}}{28}} \tag{108}$$

The spectrum $X_f$ is then quantized using:

$$X_q(n) = \begin{cases} \left\lfloor \frac{X_f(n)}{gg} + 0{,}375 \right\rfloor & \text{, if } X_f(n) \geq 0 \\ \left\lceil \frac{X_f(n)}{gg} - 0{,}375 \right\rceil & \text{, otherwise} \end{cases} \quad for \;\; n = 0 \ldots N_E - 1 \tag{109}$$

### 5.3.11.5 Bit consumption

The number of bits $nbits_{est}$ needed to encode the quantized MDCT spectrum $X_q(n)$ can be accurately estimated using the algorithm below. In the first calculation of bit consumption, the *modeFlag* is initialized to -1, whereas in a possible second calculation step after the global gain adjustment, the *modeFlag* shall be initialized to 0.

Two bitrate flags are first computed using:

```
if (nbits > (160 + f_s^ind * 160))
{
    rateFlag = 512;
}
else
{
    rateFlag = 0;
}
if (modeFlag == 0 && (nbits >= (480 + f_s^ind * 160)))
{
    modeFlag = 1;
}
else
{
    modeFlag = 0;
}
```

Then the index of the last non-zeroed 2-tuple is obtained by:

```
lastnz = N_E;
while (lastnz>2 && X_q[lastnz-1] == 0 && X_q[lastnz-2] == 0)
{
    lastnz -= 2;
}
```

The number of bits $nbits_{est}$ is then computed as follows:

```
nbits_est = 0;
nbits_trunc = 0;
nbits_lsb = 0;

if (modeFlag < 0) {
    lastnz_trunc = lastnz;
} else {
    lastnz_trunc = 2;
}
c = 0;
for (n = 0; n < lastnz; n=n+2)
{
    t = c + rateFlag;
    if (n > N_E/2)
    {
        t += 256;
    }
    a = abs(X_q[n]);
    b = abs(X_q[n+1]);

    if (modeFlag <= 0) {
        nbits_est  = nbits_est  + min(a, 1) * 2048;
        nbits_est = nbits_est  + min(b, 1) * 2048;
```

```
    }

    lev = 0;
    while (max(a,b) >= 4)
    {
        pki = ac_spec_lookup[t+lev*1024];
        nbits_est += ac_spec_bits[pki][16];
        if (lev == 0 && modeFlag == 1)
        {
            nbits_lsb += 2;
        }
        else
        {
            nbits_est += 2*2048;
        }
        a >>= 1;
        b >>= 1;
        lev = min(lev+1,3);
    }
    pki = ac_spec_lookup[t+lev*1024];
    sym = a + 4*b;
    nbits_est += ac_spec_bits[pki][sym];
    a_lsb = abs(X_q[n]);
    b_lsb = abs(X_q[n+1]);
    nbits_est += (min(a_lsb,1) + min(b_lsb,1)) * 2048;
    if (lev > 0 && modeFlag == 1)
    {
        a_lsb >>= 1;
        b_lsb >>= 1;
        if (a_lsb == 0 && X_q[n] != 0)
        {
            nbits_lsb++;
        }
        if (b_lsb == 0 && X_q[n+1] != 0)
        {
            nbits_lsb++;
        }
    }
    nbits_est += (min(a,1) + min(b,1)) * 2048;
    if (modeFlag >= 0 && (X_q[n] != 0 || X_q[n+1] != 0) && (nbits_est <= nbits_spec*2048))
    {
        lastnz_trunc = n + 2;
        nbits_trunc = nbits_est;
    }
    if (lev <= 1)
    {
        t = 1 + (a+b)*(lev+1);
    }
    else
    {
        t = 12 + lev;
    }
    c = (c&15)*16 + t;
}
nbits_est = ceil(nbits_est/2048) + nbits_lsb;
if (modeFlag >= 0) {
    nbits_trunc = ceil( nbits_trunc/2048);
} else {
    nbits_trunc = nbits_est;
}

if (modeFlag > 0) {
    nbits_est = nbits_est + nbits_lsb;
    nbits_trunc  = nbits_trunc + nbits_lsb;
}
```

with ac_lookup and ac_bits determined by the tables given in clause 5.9.6, Table 5.43.

### 5.3.11.6 Truncation

The quantized spectrum is truncated such that the number of bits needed to encode it is within the available bit budget.

```
for (k = lastnz_trunc; k < lastnz; k++)
{
    X_q[k] = 0;
}
```

with lastnz and lastnz_trunc given in clause 5.3.11.5.

A flag which allows the truncation of the LSBs in the arithmetic encoding/decoding is obtained using:

```
if (modeFlag == 1 && nbits_est > nbits_spec)
{
    lsbMode = 1;
}
else
{
    lsbMode = 0;
}
```

### 5.3.11.7 Global gain adjustment

The number of bits $nbits_{est}$ (computed in clause 5.3.11.5) is compared with the available bit budget $nbits_{spec}$ (computed in clause 5.3.11.2). If they are far from each other (as defined by the conditions given below), then the quantized global gain index $gg_{ind}$ is adjusted and the spectrum is requantized using clauses 5.3.11.4, 5.3.11.5 and 5.3.11.6. The algorithm used to adjust the quantized global gain index $gg_{ind}$ is given below. Note that the whole process is done only once. The value of $nbits_{est}^{old}$ shall not be updated if requantization is carried out.

```
if ((gg_ind < 255 && nbits_est > nbits_spec) ||
    (gg_ind > 0 && nbits_est < nbits_spec – delta2))
{
    if (nbits_est < nbits_spec – delta2)
    {
        gg_ind -= 1;
    }
    else if (gg_ind == 254 || nbits_est < nbits_spec + delta)
    {
        gg_ind += 1;
    }
    else
    {
        gg_ind += 2;
    }
    gg_ind = max(gg_ind, gg_min);
}
```

where the delta values are obtained using:

```
if (nbits_est < t1[f_s^ind])
{
    delta = (nbits_est+48)/16;
}
else if (nbits_est < t2[f_s^ind])
{
    tmp1 = t1[f_s^ind]/16+3;
    tmp2 = t2[f_s^ind]/48;
    delta = (nbits_est-t1[f_s^ind])*(tmp2-tmp1)/(t2[f_s^ind]-t1[f_s^ind]) + tmp1;
}
else if (nbits_est < t3[f_s^ind])
{
    delta = nbits_est/48;
}
else
{
    delta = t3[f_s^ind]/48;
}
delta = nint(delta);
delta2 = delta + 2;
```

and the three tables t1, t2 and t3 are given below:

```
t1[5] = {80, 230, 380, 530, 680};
t2[5] = {500, 1025, 1550, 2075, 2600};
t3[5] = {850, 1700, 2550, 3400, 4250};
```

## 5.3.12 Residual coding

Residual coding uses the remaining non-used bits to refine the non-zero quantized coefficients. It is performed only when `lsbMode` is 0.

Firstly, the maximum number of bits available for residual coding is calculated using:

```
nbits_residual_max = nbits_spec – nbits_trunc + 4;
```

Then, the residual bits are computed using:

```
k = 0;
nbits_residual = 0;
offset[2] = 0.375;

if (N_ms == 1,25)
{
    iter_max = 3;
} else {
    iter_max = 1;
}

offset[0] = offset[2] / 2;
offset[1] = (1-offset[2]) / 2;

while (iter < iter_max)
{
    while (k < N_E && nbits_residual < nbits_residual_max)
    {
        if (X_q[k] != 0)
        {
            if (X_f[k] >= X_q[k]*gg)
            {
                res_bits[nbits_residual] = 1;
                X_f[k] -= offset[X_f[idx] > 0] * gg;
            }
            else
            {
                res_bits[nbits_residual] = 0;
                X_f[k] += offset[X_f[idx] < 0] * gg;
            }
            nbits_residual++;
        }
        k++;
    }
    iter++;
    offset[0] /= 2;
    offset[1] /= 2;
}
```

## 5.3.13 Noise level estimation

### 5.3.13.1 Overview

The noise level estimator controls the noise filling on decoder side. On encoder side, the noise level parameter is estimated, quantized and transmitted in the bit stream.

### 5.3.13.2 Relevant spectral lines

The noise level is estimated based on the spectral coefficients which have been quantized to zero, i.e. $X_q(k) == 0$. The indices for the relevant spectral coefficients are given by:

$$I_{NF}(k) = \begin{cases} 1 & \text{if } NF_{start} \le k < bw_{stop} \; and \; X_q(i) == 0 \; for \; all \; i = k - NF_{width} \ldots \min(bw_{stop}, k + NF_{width}) \\ 0 & \text{otherwise} \end{cases} \quad (110)$$

where $bw_{stop}$ depends on the bandwidth detected in clause 5.3.5 as defined in Table 5.16.

**Table 5.16: Mapping table $bw_{stop}$ according to bandwidth**

| | Bandwidth ($P_{bwc}$) | | | | |
|---|---|---|---|---|---|
| | **NB** | **WB** | **SSWB** | **SWB** | **FB** |
| $bw_{stop}$ | $8 \cdot N_{ms}$ | $16 \cdot N_{ms}$ | $24 \cdot N_{ms}$ | $32 \cdot N_{ms}$ | $N_E$ |

The tuning parameters $NF_{start}$ and $NF_{width}$ are given in Table 5.17.

**Table 5.17: Tuning table for noise level estimation**

| $N_{ms}$ | $NF_{start}$ | $NF_{width}$ |
|---|---|---|
| 1,25 | 6 | 1 |
| 2,5 | 6 | 1 |
| 5 | 12 | 1 |
| 7,5 | 18 | 2 |
| 10 | 24 | 3 |

### 5.3.13.3 Noise level calculation

For the identified indices, the mean level of the missing coefficients is estimated based on the spectrum after TNS filtering ($X_f(k)$, see clause 5.3.9.4) and normalized by the global gain. If nbytes is larger than 20 or if the frame length is not 10 ms, the noise level is calculated as:

$$L_{NF} = \frac{\sum_{k=0}^{N_E-1} I_{NF}(k) \cdot \frac{|X_f(k)|}{gg}}{\sum_{k=0}^{N_E-1} I_{NF}(k)} \quad (111)$$

where $N_E$ is defined in clause 5.3.4.3. Otherwise, if the frame length is 10 ms and nbytes equals 20, two noise levels are calculated over the upper and lower half of the relevant spectral lines. To this end, a split point $k_0$ is calculated as the mean value of the relevant spectral lines, i.e.:

$$k_0 = \frac{\sum_{k=0}^{N_E-1} I_{NF}(k) \cdot k}{\sum_{k=0}^{N_E-1} I_{NF}(k)}$$

The two noise levels are then computed as:

$$L_{NF1} = \frac{\sum_{k=0}^{k_0} I_{NF}(k) \cdot \frac{|X_f(k)|}{gg}}{\sum_{k=0}^{k_0} I_{NF}(k)}$$

and

$$L_{NF2} = \frac{\sum_{k=k_0+1}^{N_E-1} I_{NF}(k) \cdot \frac{|X_f(k)|}{gg}}{\sum_{k=k_0+1}^{N_E-1} I_{NF}(k)}$$

and the final noise level is calculated as $L_{NF} = \min(L_{NF1}, L_{NF2})$.

The final noise level is quantized to eight steps:

$$F_{NF} = min(max(\lfloor 8 - 16 \cdot L_{NF} \rceil, 0), 7) \quad (112)$$

## 5.3.14 Bitstream encoding

### 5.3.14.1 Overview

The bitstream of an encoded audio frame consists of the four parts:

- initial side information;
- a dynamic data block for which is arithmetically coded;
- a dynamic data block with signs and least significant bits of the encoded spectrum;
- residual data.

An overview on the bitstream structure and layout is provided in clause 5.5. The following clauses define the exact payload writing process of all codec elements.

### 5.3.14.2 Initialization

```
bp = 0;
bp_side = nbytes – 1;
mask_side = 1;
c = 0;
nlsbs = 0;

for (i = 0; f < nbytes; i++)
{
    bytes[i] = 0;
}
```

### 5.3.14.3 Side information

#### 5.3.14.3.1 General

```
/* Bandwidth */
if (nbits_bw > 0)
{
    write_uint_backward(bytes, &bp_side, &mask_side, P_bwc, nbits_bw);
}

/* Last non-zero tuple */
lastnz_bits = ceil(log2(N_E/2));
if (((1 << lastnz_bits) - (N_E >> 1)) < 2)
{
    lastnz_bits++;
}
write_uint_backward(bytes, &bp_side, &mask_side, (lastnz_trunc >> 1) - 1, lastnz_bits);
/* LSB mode bit */
write_bit_backward(bytes, &bp_side, &mask_side, lsbMode);

/* Global Gain */
write_uint_backward(bytes, &bp_side, &mask_side, gg_ind, 8);

/* TNS activation flag */
for (f = 0; f < num_tns_filters; f++)
{
write_bit_backward(bytes, &bp_side, &mask_side, min(rc_order(f), 1));
}

/* Pitch present flag */
if (N_ms == 1,25) {
    write_LTP_data(), according to 5.3.14.3.2
} else {
    write_bit_backward(bytes, &bp_side, &mask_side, pitch_present);
}
/* SNS VQ parameters   */
if (N_ms == 1,25) {
    write_LRSNS_data(), according to 5.3.14.3.3
} else {
   /* Encode SCF VQ parameters - 1st stage (10 bits) */
```

```
   write_uint_backward(bytes, &bp_side, &mask_side, ind_LF, 5);
   write_uint_backward(bytes, &bp_side, &mask_side, ind_HF, 5);

   /* Encode SCF VQ parameters - 2nd stage side-info (3-4 bits) */
   write_bit_backward(bytes, &bp_side, &mask_side, shape_j>>1 )
   submode_LSB = (shape_j & 0x1); /* shape_j is the stage2 shape_index [0…3] */
   submode_MSB = (shape_j>>1);
   gain_MSBs   = gain_i;         /* where gain_i is the SNS-VQ stage 2 gain_index */
   gain_MSBs   = (gain_MSBs >> sns_gainLSBbits[shape_j]);
   write_uint_backward(bytes,&bp_side,&mask_side,gain_MSBs, sns_gainMSBbits[shape_j]);
   write_bit_backward(bytes, &bp_side, &mask_side, LS_indA);

   /* Encode SCF VQ parameters - 2nd stage MPVQ data   */
   if (submode_MSB == 0) {
      if (submode_LSB == 0) {
         tmp =  index_joint_0;  /*  Eq. 55 */
      } else {
         tmp =  index_joint_1;  /*  Eq. 56 */
      }
      write_uint_backward(bytes, &bp_side, &mask_side, tmp, 13)
      write_uint_backward(bytes, &bp_side, &mask_side, tmp>>13, 12);
   } else {
      if (submode_LSB == 0) {
          tmp = index_joint_2;     /* Eq. 57 */
       } else {
          tmp = index_joint_3;     /* Eq. 58 */
       }
       write_uint_backward(bytes, &bp_side, &mask_side, tmp, 12);
       write_uint_backward(bytes, &bp_side, &mask_side, tmp>> 12, 12);
   }
}

/* LTPF data */
if (pitch_present != 0 && N_ms != 1,25)
{
    write_uint_backward(bytes, &bp_side, &mask_side, ltpf_active, 1);
    write_uint_backward(bytes, &bp_side, &mask_side, pitch_index, 9);
}

/* Noise Factor */
write_uint_backward(bytes, &bp_side, &mask_side, F_NF, 3);
```

### 5.3.14.3.2 Definition of write_LTP_data() ($\mathrm{N_{ms}} = 1{,}25$)

The transmission of the LTP pitch data for $N_{ms}$ = 1,25 ms is split over two consecutive frames, i.e. phaseA and phaseB. For synchronization the data consists of header information and part of the ltpf lag(*pitch_index*) information as outlined in Table 5.17a:

**Table 5.17a: Encoding LTP data for $\mathbf{N_{ms} = 1,25}$**

| Header (*H*) | phase | pitch_present | ltpf_active | pitch_index | N bits ( H + pitch_index ) | set $TX_{LTPF}$ |
|---|---|---|---|---|---|---|
| 00 | - | 0 | 0 | | 2 + 0 | 0 |
| 010 | A | 1 | 0 | **pitch_index** >> 5 | 3 + 4 | 0x200 ^ **pitch_index** |
| 011 | B | 1 | 0 | ($TX_{LTPF}$>> 1) & 0x0F | 3 + 4 | 0 |
| 10 | A | 1 | 1 | **pitch_index** >> 5 | 2 + 4 | 0x200 ^ **pitch_index** |

### 5.3.14.3.3 Definition of write_LRSNS_data() ($\mathrm{N_{ms}} = 1{,}25$)

LRSNS-VQ 1st stage information is jointly multiplexed into 9 bits or 10 bits. The variable *stage1_idx*, has the initial stage1 CB index in the range [0 … 511], where values 510 and 511 indicate $CB_A$, values in the range 0 .. 169 indicate $CB_B$ and values in the range 170 … 339 indicate $CB_C$.

In the case of stage2 transmission, the variable *aux_idx* has the leading sign of a *set A* stage2 PVQ shape, or the first sign of any FESS shape. Variable *lrsns_idx* contains the stage2 mode information when it is non-negative, and the negated number of multiplexing bits (i.e. -9 or -10) for standalone stage1 multiplexing. Variable g*ain_idx* contains the stage2 gain level information for the shape mode corresponding to *lrsns_idx*. Variable *n5k* contains the number of PVQ unit pulses in *set A* when the incoming *lrshape_idx* is zero. Index *signs_idx* contains the signs $s_1$ and up to $s_{(Ns-1)}$ when *lrshape_idx* is corresponding to a FESS shape. Index *shift_idx* contains the 2 bit shift value when *lrshape_idx* corresponds to a FESS shape. Parameter *idxA* contains the MPVQ index for PVQ *set A* excluding the leading sign *LS_indA*. Parameter *idxB* contains the MPVQ index for PVQ segment B excl. the leading sign *LS_indB:*

```
if ( stage1_idx >= 510 ) {   /* stage1A */
    write_uint_backward_fl( bitBuffState_bw, stage1_idx, 9 ); /* 1A */
    lrshape_idx = -9; /*   only  stage 1 A , no more bits to send */
} else if ( stage1_idx < 2 * 170 ) && (lrshape_idx < 0 ) ) {
    if ( stage1_idx < 170 ) {            /* 1B */

    } else {
        fess_idx=   shift_idx << (10 -1)+ signs_idx;
        write_uint_backward_fl(bitBuffState_bw,
        (207006 >> 1) + 3 * (1 << 13) + fess_idx, 17);
    }
}
```

### 5.3.14.4 Arithmetic encoding

#### 5.3.14.4.1 Overview

The TNS data (if TNS is active) and the quantized spectral coefficients $X_q$ are noiselessly encoded. $X_q$ is encoded starting from the lowest-frequency coefficient, progressing to the highest-frequency coefficient. They are encoded by groups of two coefficients a and b resulting in a so-called 2-tuple {a, b}.

Each frequency coefficient 2-tuple {a, b} is split into three parts namely, MSB, LSB and the sign. The sign is coded independently from the magnitude using uniform probability distribution. Note that a and b may have different signs. Signs are only coded for non-zero values of a and b. The magnitude itself is further divided into two parts. The two Most Significant Bits (MSBs) of the 2-tuple {a, b} are combined and coded with an arithmetic encoder. The remaining Least Significant Bit planes (LSBs, if applicable) are encoded individually using uniform probability distribution. For 2-tuples for which the magnitude of one of the two spectral coefficients is higher than 3, one or more escape symbols are transmitted first for signalling any additional bit plane.

The relation between a 2-tuple, the individual spectral values *a* and *b* of a 2-tuple, the most significant bit planes *m* and the remaining least significant bit planes, *r*, are illustrated in the example in Figure 5.8. In this example, three escape symbols are sent prior to the actual value m, indicating three transmitted least significant bit planes.

Note that `lsbMode==1` is a special case used for high-bitrate modes where the first bit plane (lev=0) is encoded separately as residual bits.

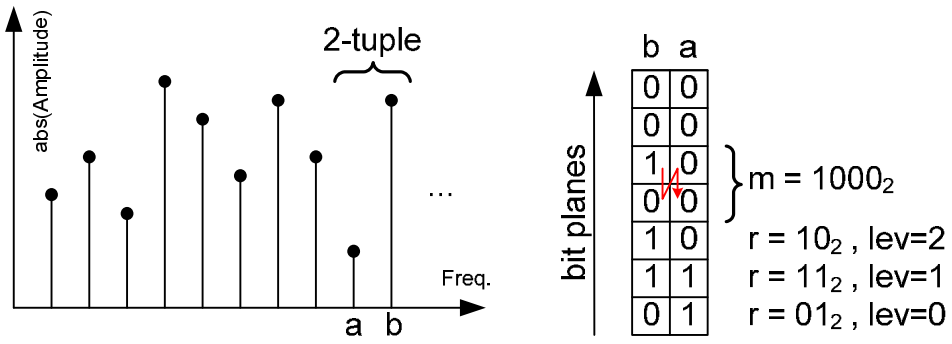

**Figure 5.8: Example of a coded pair (2-tuple) of spectral values a and b and their representation as m and r**

### 5.3.14.4.2 Pseudo code implementation

```
/* Arithmetic Encoder Initialization */
ac_enc_init(&st);

/* TNS data */
for (f = 0; f < num_tns_filters; f++)
{
    if (rc_order(f) > 0)
    {
        ac_encode(bytes, &bp, &st,
                  ac_tns_order_cumfreq[tns_lpc_weighting][rc_order(f)-1],
                  ac_tns_order_freq[tns_lpc_weighting][rc_order(f)-1]);
        for (k = 0; k < rc_order(f); k++)
        {
            ac_encode(bytes, &bp, &st, ac_tns_coef_cumfreq[k][rc_i(k,f)],
                      ac_tns_coef_freq[k][rc_i(k,f)]);
        }
    }
}

c = 0;

/* Spectral data */
for (k = 0; k < lastnz_trunc; k += 2)
{
    t = c + rateFlag;
    if (k > N_E/2)
    {
        t += 256;
    }
    a = abs(X_q[k]);
    b = abs(X_q[k+1]);
    lev = 0;
    while (max(a,b) >= 4)
    {
        pki = ac_spec_lookup[t+min(lev,3)*1024];
        ac_encode(bytes, &bp, &st, ac_spec_cumfreq[pki][16],
                  ac_spec_freq[pki][16]);
        if (lsbMode == 1 && lev == 0)
        {
            lsb0 = a & 1;
            lsb1 = b & 1;
        }
        else
        {
            write_bit_backward(bytes, &bp_side, &mask_side, a & 1);
```

```
            write_bit_backward(bytes, &bp_side, &mask_side, b & 1);
        }
        a >>= 1;
        b >>= 1;
        lev++;
    }
    pki = ac_spec_lookup[t+min(lev,3)*1024];
    sym = a + 4*b;
    ac_encode(bytes, &bp, &st, ac_spec_cumfreq[pki][sym], ac_spec_freq[pki][sym]);
    a_lsb = abs(X_q[k]);
    b_lsb = abs(X_q[k+1]);
    if (lsbMode == 1 && lev > 0)
    {
        a_lsb >>= 1;
        b_lsb >>= 1;

        }
       lsbs[nlsbs++] = lsb1;
        if (b_lsb == 0 && X_q[k+1] != 0)
        {
            lsbs[nlsbs++] = X_q[k+1]>0?0:1;
        }
    }
    if (a_lsb > 0)
    {
        write_bit_backward(bytes, &bp_side, &mask_side, X_q[k]>0?0:1);
    }
    if (b_lsb > 0)
    {
        write_bit_backward(bytes, &bp_side, &mask_side, X_q[k+1]>0?0:1);
    }
    lev = min(lev,3);
    if (lev <= 1)
    {
        t = 1 + (a+b)*(lev+1);
    }
    else
    {
        t = 12 + lev;
    }
    c = (c&15)*16 + t;
}
```

### 5.3.14.5 Residual data and finalization

```
/* Residual bits */
nbits_side = nbits – (8 * bp_side + 8 – log2(mask_side));
nbits_ari = bp * 8;
nbits_ari += 25 – floor(log2(st->range));
if (st->cache >= 0)
{
    nbits_ari += 8;
}
if (st->carry_count > 0)
{
    nbits_ari += st->carry_count * 8;
}
nbits_residual_enc = nbits – (nbits_side + nbits_ari);
if (lsbMode == 0)
{
  nbits_residual_enc = min(nbits_residual_enc, nbits_residual);
  if (N_ms == 1,25)
  {
      lMax = 3;
  } else {
      lMax = 1;
  }
  for (l = 0; l < lMax; l++){
    for (k = 0; k < nbits_residual_enc; k++)
    {
        write_bit_backward(bytes, &bp_side, &mask_side, res_bits[k]);
    }
  }
```

```
}
else
{
    nbits_residual_enc = min(nbits_residual_enc, nlsbs);
    for (k = 0; k < nbits_residual_enc; k++)
    {
        write_bit_backward(bytes, &bp_side, &mask_side, lsbs[k]);
    }
}

/* Arithmetic Encoder Finalization */
ac_enc_finish(bytes, &bp, &st);
```

where res_bits and nbits_residual are given in clause 5.3.12.

### 5.3.14.6 Functions

```
write_bit_backward(bytes[], *bp, *mask, bit)

    }
}
```

### 5.3.15 Encoding of Low Frequency Effects (LFE)

For the optimal support of a Low Frequency Effects (LFE) channel, the following encoder modules should be modified as follows:

- Bandwidth detector is deactivated and the bandwidth index $P_{bwc}$ is set to 0 (narrow band) (see clause 5.3.5).
- TNS is deactivated by setting $rc_{order}(0) = 0$, *num_tns_filters* = 1, $nbits_{TNS} = 1$ (see clause 5.3.9).
- LTPF is deactivated by setting ltpf_active to 0 (see clause 5.3.10).
- The noise level parameter $F_{NF}$ (see clause 5.3.13) is set to 7 in order to generate minimal noise filling.

## 5.4 Decoding process

### 5.4.1 Decoder modules

A high-level overview of all decoder modules is given in Figure 5.9. The decoder is reversing the encoding process and essentially transforms the spectral coefficients into a time domain signal. First the transmitted parameters are decoded and the spectral coefficients are restored. The Noise Filling module inserts noise for the coefficients that are zero and are in-band as indicated by the BW info. The coefficients are processed by the Temporal Noise Shaping (TNS) and Spectral Noise Shaping (SNS) decoders, which have taken their respective parameters from the received bitstream. The reconstructed spectral coefficients are transformed to the time domain using an Inverse LD-MDCT. Finally, the time domain signal is filtered by the Long Term Post Filter (LTPF), which uses the transmitted pitch information to define its filter.

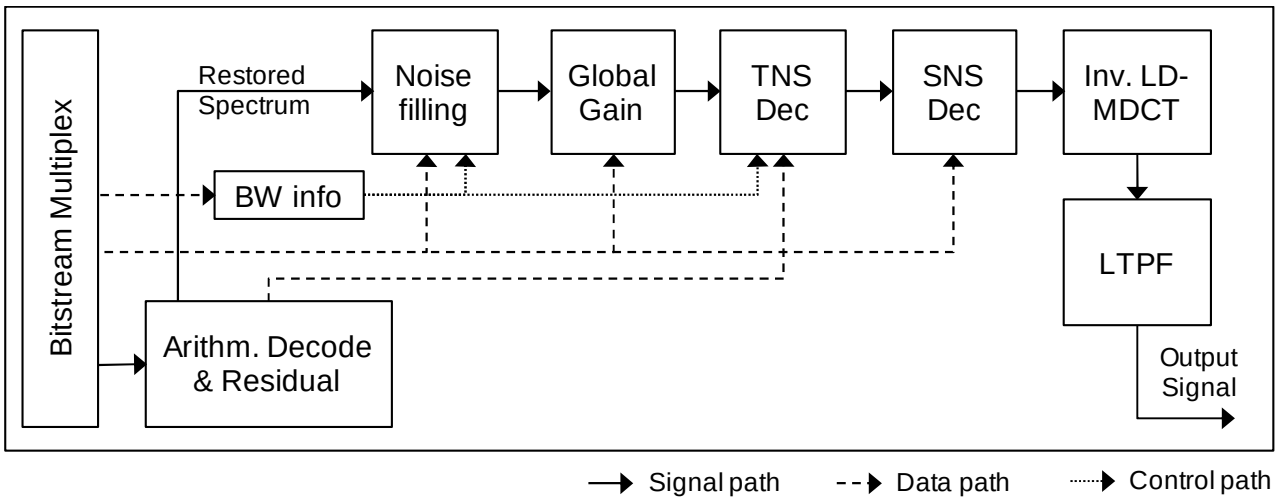

**Figure 5.9: Decoder high level overview**

## 5.4.2 Bitstream decoding

### 5.4.2.1 Overview

The bitstream of a coded audio frame consists of the four parts:

- side information;
- a dynamic data block for which is arithmetically coded;
- a dynamic data block with signs and least significant bits of the encoded spectrum;
- residual data.

An overview of the bitstream structure and layout is provided in clause 5.5. The following clauses define the exact payload reading process of all codec elements.

The decoder may detect Bit Error Conditions (BECs) in the bit stream. In the following clauses, possible locations are outlined in the bit stream where bit errors can be detected and marked as `BEC_detect=1`. In the case of positive BEC detection, the decoder shall stop parsing and apply packet loss concealment. In case special decoder modes are detected as outlined in clause 5.4.2.4, the special decoder modes shall be applied instead of packet loss concealment.

### 5.4.2.2 Initialization

```
bp = 0;
bp_side = nbytes – 1;
mask_side = 1;
c = 0;
BEC_detect = 0;
```

### 5.4.2.3 Side information

#### 5.4.2.3.1 General

```
/* Bandwidth */
if (nbits_bw > 0)
{
    P_bwc = read_uint(bytes, &bp_side, &mask_side, nbits_bw);
    if (f_s^ind < P_bwc)
    {
        BEC_detect = 1;
    }
}
else
{
    P_bwc = 0;
}

/* Last non-zero tuple */
lastnz_bits = ceil(log2(N_E/2));
if (((1 << lastnz_bits) - (N_E >> 1)) < 2)
{
    lastnz_bits++;
}
tmp_lastnz = read_uint(bytes, &bp_side, &mask_side, lastnz_bits);
lastnz = (tmp_lastnz + 1) << 1;
if (lastnz > N_E)
{
    /* check for special decoder modes, see clause 5.4.2.4; if no
      special mode detected, consider this as bit error (BEC) */
    BEC_detect = 1;
}

/* LSB mode bit */
lsbMode = read_bit(bytes, &bp_side, &mask_side);

/* Global Gain */
gg_ind = read_uint(bytes, &bp_side, &mask_side, 8);
```

```
/* TNS activation flag */
if (P_bwc < 3)
{
    num_tns_filters = 1;
}
else
{
    num_tns_filters = 2;
}
if (N_ms === 1,25)
{
    tns_num_filters = 0;
}
for (f = 0; f < num_tns_filters; f++)
{
     rc_order(f) = read_bit(bytes, &bp_side, &mask_side);
}

/* Pitch present flag */
if (N_ms == 1,25) {
    read_LTP_data(), according to 5.4.2.3.2
} else {
    pitch_present = read_bit(bytes, &bp_side, &mask_side);
}

if (N_ms == 1,25) {
    /* LR SNS-VQ bits */
    /* Read one of {9,10, 29 or 30} LR SNS bits  according to clause 5.4.7.2a */
} else {
    /* SNS-VQ integer bits */
    /* Read 5+5 bits of SNQ VQ stage 1 according to clause 5.4.7.2.2 */
    /* Read 28 bits of SNQ VQ stage 2 according to clause 5.4.7.2.3 */
}
/* LTPF data */
if (pitch_present != 0 && N_ms! = 1,25)
{
    ltpf_active = read_uint(bytes, &bp_side, &mask_side, 1);
    pitch_index = read_uint(bytes, &bp_side, &mask_side, 9);
}
else
{
    pitch_index = 0;
    ltpf_active = 0;
}

/* Noise Level */
F_NF = read_uint(bytes, &bp_side, &mask_side, 3);
```

### 5.4.2.3.2 Definition of read_LTP_data() ($N_{ms} = 1,25$)

The transmission of the LTP data for $N_{ms}$ = 1,25 ms is split over two consecutive frame, i.e. phaseA and phaseB. For synchronization, the data consists of header information H of 2 bits. If the value of H is 1, one more bit shall be read and added to the header. Table 5.17b lists the interpretation of phase, pitch_present and ltpf_active depending on the header.

**Table 5.17b: Decoding LTP data for $N_{ms} = 1,25$**

| Header ($H$) | phase | pitch_present | ltpf_active | pitch_index_bits |
|---|---|---|---|---|
| 00 | - | 0 | 0 | |
| 010 | A | 1 | 0 | 4 |
| 011 | B | 1 | 0 | 4 |
| 10 | A | 1 | 1 | 4 |
| 11 | B | 1 | 1 | 5 |

Depending on the phase, the pitch_index bits are to be stored in auxiliary variables $pitchInfo_A$ or $pitchInfo_B$. The pitch_index is to be constructed in phase B (in the cases that phase B was preceded by an adjacent phaseA reception of $pitchInfo_A$) by:

$$\text{pitch_index} = \begin{cases} (pitchInfo_A \ll 5) \mid (pitchInfo_B \ll 1), if\ H = 011 \\ (pitchInfo_A \ll 5) \mid (pitchInfo_B), if\ H = 11 \end{cases} \quad (112.1)$$

### 5.4.2.4 Special decoder mode indicators

The indicated modes in this clause may be set by an external application layer to trigger a specific behaviour of the decoder, e.g. the decoder shall apply packet loss concealment due to a broken payload.

For that, the bit stream element `tmp_lastnz` (see clause 5.4.2.3) is used to indicate that the decoder shall operate in special mode. For signalling the mode, some non-meaningful values of `tmp_lastnz` are used according to Table 5.18.

**Table 5.18: Special decoder mode indicators**

| Lastnz | Mode | Meaning |
|---|---|---|
| MAXnz | PLC | Apply Packet Loss Concealment |
| MAXnz - 1 | PADDING | Padding pattern need to be removed before frame starts, see clause 5.4.2.5 |
| MAXnz - 2 | DTX | Apply Discontinuous Transmission |
| … | RESERVED | |
| MAXnz - 7 | RESERVED | |

Where MAXnz is the maximum possible value of `tmp_lastnz` according to the used sampling rate as outlined in Table 5.19.

**Table 5.19: Maximum value of tmp_lastnz according to sampling rate**

| | MAXnz($N_{ms}, f_s$) | | | | |
|---|---|---|---|---|---|
| $f_s$ | $f_s$ = 8 000 Hz | $f_s$ =16 000 Hz | $f_s$ = 24 000 Hz | $f_s$ = 32 000 Hz | $f_s$ = 44 100 Hz, 48 000 Hz |
| $N_{ms}$ = 1,25 | --- | 15 | 31 | 31 | 31 |
| $N_{ms}$ = 2, 5 | 15 | 31 | 31 | 63 | 63 |
| $N_{ms}$ = 5 | 31 | 63 | 63 | 127 | 127 |
| $N_{ms}$ = 7,5 | 31 | 63 | 127 | 127 | 255 |
| $N_{ms}$ = 10 | 63 | 127 | 127 | 255 | 255 |

In case, the behaviour of a certain special decoder mode is not known by the decoder, the decoder shall set BFI=1 and apply PLC.

### 5.4.2.5 Padding pattern

For specific transport scenarios a padding might be required to reach a certain frame size. At decoder side this pattern needs to be removed before the side information can be interpreted. In case the special mode PADDING is detected, the decoder shall read the remaining bits to complete the first two bytes of the side information. The meaning of the two bytes is outlined in Table 5.20.

**Table 5.20: Padding signalling as part of side information. Bandwidth bits read first followed by Lastnz bits, padding length bits and reserved bits**

| Reserved bits | Padding length bits | Lastnz bits | Bandwidth bits |
|---|---|---|---|
| 4 bits | 16 - Lastnz bits - bandwidth bits - Reserved bits | ceil(log2($N_E$/2)) | $nbits_{bw}$ |

The padding length bits determine the number of bytes to be skipped. The decoding process starts again reading the side information at the new bit stream position. The procedure may be repeated multiple times in case the intended padding size cannot be signalled by the available padding length bits. Padding bits shall not have any influence on the bit rate parameter for controlling the tuning settings for dedicated bit rates. This means after removal of padding bits, the real codec bit rate shall be determined and the tuning parameters shall be updated as done for external rate adaptation described in clause 5.7.

NOTE: The minimum padding size is two bytes. The maximum is not limited, however if the remaining frame size has less than 20 bytes, i.e. the minimum LC3plus frame size, the frame is considered as corrupt.

### 5.4.2.6 Bandwidth interpretation

Depending on the transmitted parameter $P_{bwc}$ (see clause 5.4.2.3) and the sample frequency $f_s$, the bandwidth information can be interpreted as outlined in Table 5.21.

**Table 5.21: Mapping $P_{bwc}$ to bandwidth**

| $f_s$ (Hz) | $nbits_{bw}$ | Bandwidth ($P_{bwc}$) |
|---|---|---|
| 8 000 | 0 | {NB} |
| 16 000 | 1 | {NB, WB} |
| 24 000 | 2 | {NB, WB, SSWB} |
| 32 000 | 2 | {NB, WB, SSWB, SWB} |
| 44 100, 48 000 | 3 | {NB, WB, SSWB, SWB, FB} |

### 5.4.2.7 Arithmetic decoding

```
/* Arithmetic Decoder Initialization */
ac_dec_init(bytes, &bp, &st);

/* TNS data */
maxTnsOrder = 8;
if N_ms <= 5
{
  maxTnsOrder = maxTnsOrder >> 1
}
for (f = 0; f < num_tns_filters; f++)
{
    if (rc_order(f) > 0)
    {
        rc_order(f) = ac_decode(bytes, &bp, &st,
                          ac_tns_order_cumfreq[tns_lpc_weighting],
                          ac_tns_order_freq[tns_lpc_weighting], 8,
                          &BEC_detect);
        rc_order(f) = rc_order(f)  + 1;
        for (k = 0; k < 8; k++)
        {
            rc_i(k,f) = 8;
        }
        if rc_order(f) > maxTnsOrder
        {
            BEC_detect = 1;
        }
        for (k = 0; k < rc_order(f); k++)
        {
            rc_i(k,f) = ac_decode(bytes, &bp, &st, ac_tns_coef_cumfreq[k],
                              ac_tns_coef_freq[k], 17, &BEC_detect);
        }
    }
}

/* Spectral data */
for (k = 0; k < lastnz; k += 2)
{
    t = c + rateFlag;
    if (k > N_E/2)
    {
        t += 256;
    }
    X_q^[k] = X_q^[k+1] = 0;
    for (lev = 0; lev < 14; lev++)
    {
        pki = ac_lookup[t+min(lev,3)*1024];
        sym = ac_decode(bytes, &bp, &st, ac_spec_cumfreq[pki],
                        ac_spec_freq[pki], 17, &BEC_detect);
        if (sym < 16)
        {
            break;
        }
        if (lsbMode == 0 || lev > 0)
        {
            bit = read_bit(bytes, &bp_side, &mask_side);
            X_q^[k] += bit << lev;
```

```
            bit = read_bit(bytes, &bp_side, &mask_side);
            X̂_q[k+1] += bit << lev;
        }
    }
    if (lev == 14)
    {
        BEC_detect = 1;
    }
    if (lsbMode == 1)
    {
        save_lev[k] = lev;
    }
    a = sym & 0x3;
    b = sym >> 2;
    X̂_q[k] += a << lev;
    X̂_q[k+1] += b << lev;
    if (X̂_q[k] > 0)
    {
        bit = read_bit(bytes, &bp_side, &mask_side);
        if (bit == 1)
        {
            X̂_q[k] = -X̂_q[k];
        }
    }
    if (X̂_q[k+1] > 0)
    {
        bit = read_bit(bytes, &bp_side, &mask_side);
        if (bit == 1)
        {
            X̂_q[k+1] = -X̂_q[k+1];
        }
    }
    lev = min(lev,3);
    if (lev <= 1)
    {
        t = 1 + (a+b)*(lev+1);
    }
    else
    {
        t = 12 + lev;
    }
    c = (c&15)*16 + t;
    if (bp – bp_side > 3 || BEC_detect == 1)
    {
        BEC_detect = 1;
    }
}
```

### 5.4.2.8 Residual data and finalization

```
for (k = lastnz; k < N_E; k++)
{
    X̂_q[k] = 0;
}

/* Number of residual bits */
nbits_side = nbits – (8 * bp_side + 8 – log2(mask_side));
nbits_ari = (bp – 3) * 8;
nbits_ari += 25 – floor(log2(st->range));
nbits_residual = nbits – (nbits_side + nbits_ari);
if (nbits_residual < 0)
{
    BEC_detect = 1;
}

/* Decode residual bits */
if (lsbMode == 0)
{
    nResBits = 0;
    lMax = 1;
    if (N_ms == 1,25)
    {
        lMax = 3;
    }
    for (l = 0; l < lMax; l++)
    {
```

```
      for (k = 0; k < N_E; k++)
      {
        if (X̂_q[k] != 0)
        {
            if (nResBits == nbits_residual)
            {
                break;
            }
            resBits[nResBits++] = read_bit(bytes, &bp_side, &mask_side);
        }
      }
    }
}
else
{
    for (k = 0; k < lastnz; k+=2)
    {
        if (save_lev[k] > 0)
        {
            if (nbits_residual == 0)
            {
                break;
            }
            bit = read_bit(bytes, &bp_side, &mask_side);
            nbits_residual--;
            if (bit == 1)
            {

                }
                else if (X̂_q[k+1] < 0)
                {
                    X̂_q[k+1] -= 1;
                }
                else
                {
                    if (nbits_residual == 0)
                    {
                        break;
                    }
                    bit = read_bit(bytes, &bp_side, &mask_side);
```

```
                    nbits_residual--;
                    if (bit == 0)
                    {
                        X̂_q[k+1] = 1;
                    }
                    else
                    {
                        X̂_q[k+1] = -1;
                    }
                }
            }
        }
    }
}

/* Noise Filling Seed */
tmp = 0;
for (k = 0; k < N_E; k++)
{
    tmp += abs(X̂_q[k]) * k;
}
nf_seed = tmp & 0xFFFF; /* Note that tmp is a 32-bit signed int and nf_seed is an unsigned 16-bit
int */

/* Zero frame flag */
if (lastnz == 2 && X̂_q[0] == 0 && X̂_q[1] == 0 && gg_ind == 0 && F_NF == 7)
{
    zeroFrame = 1;
}
else
{
    zeroFrame = 0;
}
```

### 5.4.2.9 Functions

```
read_bit(bytes[], *bp, *mask)
{
    if (bytes[*bp] & *mask)
    {
        bit = 1;
    }
    else
    {
        bit = 0;
    }
    if (*mask == 0x80)
    {
        *mask = 1;
        *bp -= 1;
    }
    else
    {
        *mask <<= 1;
    }
    return bit;
}

read_uint(bytes[], *bp, *mask, numbits)
{
    value = read_bit(bytes, bp, mask);
    for (i = 1; i < numbits; i++)
    {
        bit = read_bit(bytes, bp, mask);
        value += bit << i;
    }
    return value;
}

ac_dec_init(bytes[], *bp, *st)
{
    st->low = 0;
    st->range = 0x00ffffff;
    for (i = 0; i < 3; i++)
    {
        st->low <<= 8;
```

```
        st->low += bytes[(*bp)++];
    }
}

ac_decode(bytes[], *bp, *st, cum_freq, sym_freq, numsym, *BEC_detect)
{
    tmp = st->range >> 10;
    if (st->low >= (tmp<<10))
    {
        *BEC_detect = 1;
    }
    val = numsym-1;
    while (st->low < tmp * cum_freq[val])
    {
        val--;
    }
    st->low -= tmp * cum_freq[val];
    st->range = tmp * sym_freq[val];
    while (st->range < 0x10000)
    {
        st->low <<= 8;
        st->low &= 0x00ffffff;
        st->low += bytes[(*bp)++];
        st->range <<= 8;
    }
    return val;
}
```

## 5.4.3 Residual decoding

Residual decoding is performed only when `lsbMode` is 0.

```
iter = k = n = 0;
iter_max = 1;
if (N_ms == 1,25)
{
    iter_max = 3;
}
while (iter < iter_max && n < nResBits)
{
  while (k < N_E )
  {
    if (X̂_q[k] != 0)
    {
        if (resBits[n++] == 0)
        {
            if (X̂_q[k] > 0)
            {
                X̂_q[k] -= 0.1875;
            }
            else
            {
                X̂_q[k] -= 0.3125;
            }
        }
        else
        {
            if (X̂_q[k] > 0)
            {
                X̂_q[k] += 0.3125;
            }
            else
            {
                X̂_q[k] += 0.1875;
            }
        }
    }
    k++;
  }
  iter++;
}
```

## 5.4.4 Noise filling

Noise filling is performed only when `zeroFrame` is 0.

The indices for the relevant spectral coefficients are given by:

$$I_{NF}(k) = \begin{cases} 1 & \text{if } NF_{start} \le k < bw_{stop} and\ \widehat{X_q}(i) == 0\ for\ all\ i = k - NF_{width} .. \min\left(bw_{stop}, k + NF_{width}\right) \\ 0 & \text{otherwise} \end{cases} \quad (113)$$

where $bw_{stop}$ depends on the bandwidth information (see clause 5.4.2.4) as defined in Table 5.22.

**Table 5.22: Mapping table $bw_{stop}$ according to bandwidth**

| | Bandwidth ($P_{bwc}$) | | | | |
|---|---|---|---|---|---|
| | **NB** | **WB** | **SSWB** | **SWB** | **FB** |
| $bw_{stop}$ | $8 \cdot N_{ms}$ | $16 \cdot N_{ms}$ | $24 \cdot N_{ms}$ | $32 \cdot N_{ms}$ | $N_E$ |

The tuning parameters $NF_{start}$ and $NF_{width}$ are given in Table 5.23.

**Table 5.23: Tuning table for noise level estimation**

| $N_{ms}$ | $NF_{start}$ | $NF_{width}$ |
|---|---|---|
| 1,25 | 6 | 1 |
| 2,5 | 6 | 1 |
| 5 | 12 | 1 |
| 7,5 | 18 | 2 |
| 10 | 24 | 3 |

The noise filling is applied on the identified relevant spectral lines $I_{NF}(k)$ using the transmitted noise factor $F_{NF}$ given in clause 5.4.2.3 and the random seed (nf_seed) given in clause 5.4.2.8.

```
L_NF = (8-F_NF)/16;
for k=0..bw_stop-1
  if I_NF(k)==1
    nf_seed = (13849+nf_seed*31821) & 0xFFFF;
    if nf_seed<0x8000
      X_q(k) = L_NF;
    else
      X_q(k) = -L_NF;
```

## 5.4.5 Global gain

The global gain is applied to the spectrum after the noise filling has been applied using formula (114):

$$\widehat{X_f}(k) = \widehat{X_q}(k) \cdot 10^{\left(\frac{gg_{ind} + gg_{off}}{28}\right)} \quad for\ k = 0 \ldots N_E - 1 \quad (114)$$

where $gg_{ind}$ is the global gain index retrieved in the side information described in clause 5.4.2.3, and:

$$gg_{off} = -\min\left(115, \left\lfloor \frac{nbits}{10 \cdot (f_s^{ind} + 1)} \right\rfloor\right) - 105 - 5 \cdot (f_s^{ind} + 1) \quad (115)$$

## 5.4.6 TNS decoder

The quantized reflection coefficients are obtained for each TNS filter $f$ using:

$$rc_q(k, f) = \frac{\text{nint}[2^{15} \cdot \sin[\Delta(rc_i(k, f) - 8)]]}{2^{15}} \quad k = 0 \ldots 7 \quad (116)$$

with $rc_i(k, f)$ are the quantizer output indices.

The TNS parameters depend on the transmitted bandwidth information (see clause 5.4.2.4) as shown in Table 5.24.

**Table 5.24: TNS decoder parameters**

| $N_{ms}$ | Bandwidth | num_tns_filters | start_freq(f) | stop_freq(f) |
|---|---|---|---|---|
| 2,5 | NB | 1 | {3} | {20} |
| 2,5 | WB | 1 | {3} | {40} |
| 2,5 | SSWB | 1 | {3} | {60} |
| 2,5 | SWB | 1 | {3} | {80} |
| 2,5 | FB | 1 | {3} | {100} |
| 5 | NB | 1 | {6} | {40} |
| 5 | WB | 1 | {6} | {80} |
| 5 | SSWB | 1 | {6} | {120} |
| 5 | SWB | 2 | {6, 80} | {80, 160} |
| 5 | FB | 2 | {6, 100} | {100, 200} |
| 7,5 | NB | 1 | {9} | {60} |
| 7,5 | WB | 1 | {9} | {120} |
| 7,5 | SSWB | 1 | {9} | {180} |
| 7,5 | SWB | 2 | {9, 120} | {120, 240} |
| 7,5 | FB | 2 | {9, 150} | {150, 300} |
| 10 | NB | 1 | {12} | {80} |
| 10 | WB | 1 | {12} | {160} |
| 10 | SSWB | 1 | {12} | {240} |
| 10 | SWB | 2 | {12, 160} | {160, 320} |
| 10 | FB | 2 | {12, 200} | {200, 400} |

The MDCT spectrum $\widehat{X_f}(n)$ as generated in clause 5.4.5 is then filtered using the following algorithm:

```
for n = 0 to N_E-1 do
        X̂_s(n) = X̂_f(n)

s^0 = s^1 = ··· = s^7 = 0
for f = 0 to num_tns_filters-1 do
    if (rc_order(f) > 0)
        for n = start_freq(f) to stop_freq(f) − 1 do
            t = X̂_f(n) − rc_q(rc_order(f) − 1, f) · s^(rc_order(f)−1)
            for k = rc_order(f) − 2 to 0 do
                t = t − rc_q(k, f) · s^k
                s^(k+1) = rc_q(k, f) · t + s^k
                X̂_s(n) = t
            s^0 = t
```

where $\widehat{X_s}(n)$ is the output of the TNS decoder.

## 5.4.7 SNS decoder

### 5.4.7.1 Overview

The SNS decoder performs the following three steps. A set of 16 quantized scale factors is first decoded as described in clause 5.4.7.2. Note that these quantized scale factors are the same as the quantized scale factors as determined by the encoder (see clause 5.3.7.3). Similarly to the encoder (see clauses 5.3.7.4 and 5.3.7.5), the quantized scale factors are then interpolated as described in clause 5.4.7.3 and used to shape the MDCT spectrum as described in clause 5.4.7.4.

### 5.4.7.2 SNS scale factor decoding

#### 5.4.7.2.1 SNS VQ decoding

Figure 5.10 provides an overview of the SNS scale factor decoding.

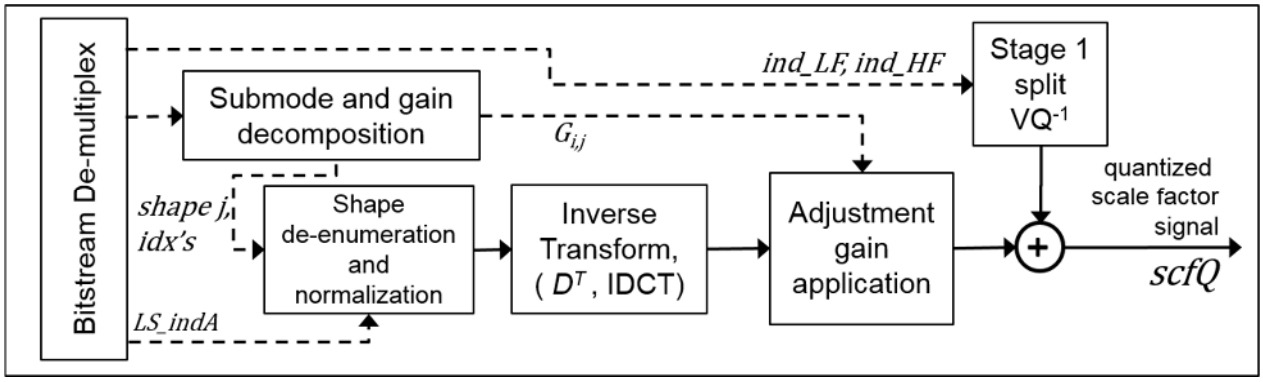

**Figure 5.10: High level overview of Decoder SNS scale factor synthesis**

#### 5.4.7.2.2 Stage 1 SNS VQ decoding

The first stage parameters are decoded as follows:

```
    ind_LF = read_uint(bytes, &bp_side, &mask_side, 5); /* stage1 LF  */
    ind_HF = read_uint(bytes, &bp_side, &mask_side, 5); /* stage1 HF  */
```

The first stage indices *ind_LF* and *ind_HF* are converted into signal *st1(n)* according to equations (36) and (37) in clause 5.3.7.3.2.

#### 5.4.7.2.3 Stage 2 SNS VQ decoding

##### 5.4.7.2.3.1 Stage 2 SNS-VQ index demultiplexing

To efficiently use the available total bit space for the scale factor quantizer (38 bits), in combination with the fractional sized MPVQ-indices, the shape selection LSB, the second stage shape codewords and the adjustment gain least significant bit were jointly encoded as described in Table 5.14 and the subsequent paragraph in the encoder clause 5.3.7.3.4.

On the decoder/receiver side the reverse process takes place.

The second stage MSB submode bit, initial gain index and the Leading Sign index are first read from the decoded bitstream as follows:

```
submodeMSB = read_bit(bytes, &bp_side, &mask_side);
if( submodeMSB == 0 ){
   Gind       = read_uint(bytes, &bp_side, &mask_side, 1);
} else {
   Gind       = read_uint(bytes, &bp_side, &mask_side, 2);
}
LS_indA     = read_bit(bytes, &bp_side, &mask_side); /*  LS_indA 1 bit */
```

If *submodeMSB* equals 0, corresponding to one of the shapes *(shape_j = 0* or *shape_j = 1)*, the following demultiplexing procedure is performed:

```
/* 'regular'/'regular_lf' demultiplexing, establish if shape_j is 0 or 1 */

tmp =   read_uint(bytes, &bp_side, &mask_side, 13) ;
tmp |= (read_uint(bytes, &bp_side, &mask_side, 12)<<13) ;
[ BEC_detect, submodeLSB, idxA, idxBorGainLSB ] =
    dec_split_st2VQ_CW(tmp,  4780008U>>1,  14 );

if(  submodeLSB != 0 ) {
   Gind    = (Gind<<1) + idxBorGainLSB; /* for regular_lf   */
} else {
   idxB    = idxBorGainLSB>>1;          /* for regular */
   LS_indB = idxBorGainLSB&0x1);
}
```

with function dec_split_st2VQ_CW defined as:

```
[BEC_detect, submodeLSB, idxA, idxBorGainLSB ] =
 dec_split_st2VQ_CW(cwRx, szA, szB )
{
    if( cwRx  >=    szB * szA) {
        idxA                = 0;
        idxBorGainLSB       = 0;
        submodeLSB          = 0;
        BEC_detect          = 1;
        return;
    }

    idxBorGainLSB  =   floor( cwRx / szA );
    idxA           =   cwRx – idxBorGainLSB*szA;

    submodeLSB    = 0;
    idxBorGainLSB =  idxBorGainLSB – 2 ;
    if( idxBorGainLSB < 0 ) {
         submodeLSB = 1;
    }
    idxBorGainLSB  =  idxBorGainLSB + 2*submodeLSB ;

    BEC_detect     = 0;

    return;
}
```

If *submodeMSB* equals 1, ('outlier_near' or 'outlier_far' submodes) the following demultiplexing procedure is performed:

```
/* outlier_* demultiplexing, establish if shape_j is 2 or 3  */

tmp =   read_uint(bytes, &bp_side, &mask_side, 12);
tmp |= ( read_uint(bytes, &bp_side, &mask_side, 12)<<12 );

idxA       = tmp;
idxB       = -1;
submodeLSB = 0;
BEC_detect = 0;

if ( tmp  >=    ((30316544U>>1)  +  1549824U) ) {
   BEC_detect = 1;
} else {
   tmp            -= (30316544U>>1);
   if( tmp >= 0 )  {
      submodeLSB     = 1;
      Gind           = (Gind<<1) + (tmp&0x1);
      idxA           = tmp>>1;
   }
}
```

Finally the decombined/demultiplexed second stage indices *shape_j* and *gain_i* are determined as follows:

```
shape_j    = (submodeMSB<<1) + submodeLSB;
gain_i     = Gind;
```

#### 5.4.7.2.3.2 De-enumeration of the shape indices

If *shape_j* is 0, the two shapes *A* and *B*, (where shape *A* is a function of *LS_indA* and *idxA*, and shape *B* is a function of *LS_indB and idxB)* are de-enumerated into signed integer vectors, otherwise (*shape_j* is not 0) only one shape is de-enumerated. The setup of the four possible shape configurations is described in Table 5.9.

The actual de-enumeration of a leading sign index *LS_ind* and an MPVQ shape index *MPVQ_ind* into a signed integer PVQ vector $y (= vec_out)$ with an L1 norm of $K (= k_val_in)$ over dimension $N (= dim_in)$, is shown in C-style pseudo code below.

```
MPVQdeenum( dim_in,      /* i :  dimension of vec_out     */
            k_val_in,    /* i :  number of unit pulses    */
            LS_ind,      /* i :  leading sign index       */
            MPVQ_ind,    /* i :  MPVQ shape index         */
            *vec_out     /* o :  PVQ integer pulse train  */
{
  for (i=0; i < dim_in; i++){
```

```
     vec_out[i] = 0;
  }

  leading_sign = 1;
  if ( LS_ind != 0 ){
        leading_sign = -1;
  }

  mind2vec_tab ( dim_in,
                 k_val_in,
                 leading_sign,
                 MPVQ_ind,
                 vec_out,
                 MPVQ_offsets );
  return;
}
```

with:

```
mind2vec_tab ( short        dim_in,       /* i:  dimension        */
               short        k_max_local,  /* i:  nb unit pulses   */
               short        leading_sign, /* i:  leading sign     */
               unsigned int ind,          /* i:  MPVQ-index       */
               short        *vec_out,      /* o:  pulse train      */
               unsigned int  MPVQ_offsets [][11]     /* i:  offset matrix    */
)
{
    /* init */
    h_row_ptr = &(MPVQ_offsets[(dim_in-1)][0]);
    k_acc     = k_max_local;

    /* loop over positions */
    for (pos = 0; pos < dim_in; pos++) {

        if (ind != 0) {
            k_acc         = k_max_local;;
            UL_tmp_offset = h_row_ptr[k_acc];

            wrap_flag   = (ind < UL_tmp_offset ) ;
            UL_diff     =  ind - UL_tmp_offset;

            while (wrap_flag != 0) {
                k_acc--;
                wrap_flag = (ind <  h_row_ptr[k_acc]);
                UL_diff   =  ind -  h_row_ptr[k_acc];
            }

            ind     = UL_diff;
            k_delta = k_max_local - k_acc;
        } else {
            mind2vec_one(k_max_local, leading_sign, &vec_out[pos]);
            break;
        }

        k_max_local = setval_update_sign(
                      k_delta,
                      k_max_local,
                      &leading_sign,
                      &ind,
                      &vec_out[pos]);
        h_row_ptr -= 11;      /* reduce dimension in MPVQ_offsets table */
    }
    return;
}
```

with:

```
mind2vec_one( short  k_val_in,      /* i:  nb unit pulses  */
              short  leading_sign,  /* i: leading sign  -1, 1 */
              short *vec_out        /* o:  updated pulse train   */
)
{
    amp =  k_val_in;
    if ( leading_sign < 0 )
    {
        amp = -k_val_in ;
    }
    *vec_out = amp;
```

```
    return;
}
```

with:

```
[ k_max_local_out ] = setval_update_sign (
    short k_delta,         /* i  */
    short k_max_local_in,  /* i  */
    short *leading_sign,   /* i/o */
    unsigned int  *ind_in,         /* i/o */
    short *vec_out         /* i/o */
)
{
    k_max_local_out = k_max_local_in;
    if  (k_delta != 0) {
        mind2vec_one(k_delta, *leading_sign, vec_out);
        *leading_sign      = get_lead_sign( ind_in );
        k_max_local_out   -=  k_delta ;
    }
    return k_max_local_out;
}
```

with:

```
[ leading_sign ] =  get_lead_sign(unsigned int  *ind_in )
{
    leading_sign     =  +1;
    if ( ((*ind)&0x1 ) != 0 ) {
        leading_sign =  -1;
    }
    (*ind) = (*ind >> 1);

    return leading_sign;
}
```

The `MPVQdeenum()` function above uses a table based approach to decompose the two input indices into a signed integer PVQ vector with L1 norm of `k_val_in` and a leading sign for the first non-zero element according to the `LS_ind` index. As the encoder side enumeration was performed from the end of the vector to the start of the vector the de-enumeration takes place from the start(0) to the end (`dim_in-1`) of the vector.

The following MPVQ de-enumeration calls are made for the demultiplexed *shape_j*.

**Table 5.25: SNS VQ second stage shape de-enumeration into integer vector $y_{shape_j}$ for each possible received shape index *shape_j***

| Shape index (*shape_j*) | Shape name | Scale factor set A de-enumeration | Scale factor set B de-enumeration (or initialization) |
|---|---|---|---|
| 0 | 'regular' | MPVQdeenum(*10, 10, $y_0$, LS_indA, idxA*) | MPVQdeenum(*6, 1, z, LS_indB, idxB*); $y_0(n) = z(n-10)$, *for n=10...15* |
| 1 | 'regular_lf' | MPVQdeenum(*10, 10, $y_1$, LS_indA, idxA*) | $y_1(n) = 0$, *for n=10...15* |
| 2 | 'outlier_near' | MPVQdeenum(*16, 8, $y_2$, LS_indA, idxA*) | n/a |
| 3 | 'outlier_far' | MPVQdeenum(*16, 6, $y_3$, LS_indA, idxA*) | n/a |

### 5.4.7.2.4 Unit energy normalization of the received shape

The de-enumerated signed integer vector $y_{shape_j}$ is normalized to a unit energy vector $x_{q,\ shape_j}$ over dimension 16 according to equation (41).

### 5.4.7.2.5 Reconstruction of the Quantized SNS Scalefactors

The adjustment gain value $G_{gain_i,shape_j}$ for gain index *gain_i* and shape index *shape_j* is determined based on table lookup (see clause 5.3.7.3.3.6, Table 5.11).

Finally, the synthesis of the quantized scale factor vector *scfQ(n)* is performed in the same way as on the encoder side, see clause 5.3.7.3.5.

## 5.4.7.2a Low Rate SNS scale factor decoding

### 5.4.7.2a.1 Low Rate SNS VQ decoding

Figure 5.10a provides an overview of the Low Rate SNS scale factor decoding.

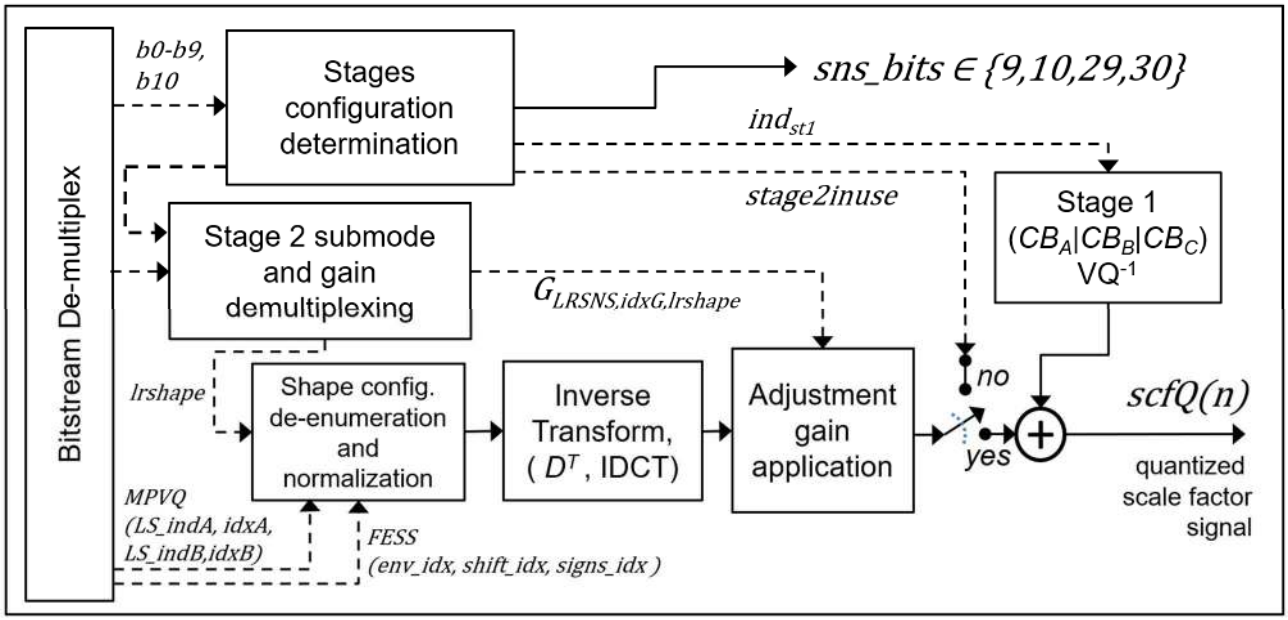

**Figure 5.10a: High level overview of Low Rate SNS Decoder scale factor synthesis**

### 5.4.7.2a.2 Low Rate SNS configuration and Stage 1 SNS VQ decoding

The low rate first stage parameters are decoded sequentially from 9 or 10 initial bits as follows:

```
ind         = read_uint(bytes, &bp_side, &mask_side, 9); /* stage1 b0…b8 */

if( ind >= 510 ) {
    sns_bits    = 9;
    indA        = ind - 510; /* range 0 ... 1 */
    stage2inuse = 0;
} else {
    stopBit     = read_uint(bytes, &bp_side, &mask_side, 1); /* b9, stage1 stopBit*/
    if ( stopBit && ind < 340 )
    {
        stage2inuse = 0;
        sns_bits    = 10;
        if (ind >= 170) {
            indC = ind-170;
        }
    }  else {
        stage2inuse = 1;
        sns_bits = 29;
        if( ind >= 340 )  {
            sns_bits = 30;
        }
    }
}
```

If *ind* ∈ [510 ... 511], only $CB_A$ is present in the bit stream and the first stage indice *indA* is converted into an *M*-dimensional signal $st1_{indA}(n)$ according to encoder clause 5.3.7.3a.5.1.

If *ind* ∈ [0 ... 510], then the *stopBit* is used do determine the presence of $CB_B$ , $CB_C$ or the combination of $CB_B$ and Stage 2.

If *ind* ∈ [0 ... 169] and *stopBit*==1, then only $CB_B$ is present in the bit stream, *indB* is set to *ind* , *stage2use* is set to *0* and the first stage indice *indB* is converted into an *M*-dimensional signal $st1_{indB}(n)$ according encoder synthesis part of clause 5.3.7.3a.2.2. Additionally the DC is removed from $st1_{indB}(n)$ to generate $st1_{indB,noDC}(n)$ according to encoder clause (59.4 ).

If *ind* ∈ [170 ... 339] and *stopBit*==1, then only $CB_C$ is present in the bit stream, *indC* is set to *ind-170* , *stage2use* is set to *0* and the first stage indice *indC*, accompanied by the received binary flags $pitch_{rx}$ (==*pitch_present*) and $ltpf_{rx}$ (==*ltpf_active*) is converted into an *M*-dimensional signal $st1_{indC}(n)$ according to encoder clause 5.3.7.3a.5.1 and equation (59.12)

If the *stopBit* value is zero or the *stopBit* value is one and *ind* ∈ [340 ... 509], then *stage2use* is set to *1*.

Available stage 1 $CB_B$ and stage 2 combinations and the auxiliary bit value 'aux' are now given by the remaining codespace for bits b0 through b9 , i.e. stopBit==0, ind ∈ [0 ... 510] and stopBit==1, ind ∈ [340 ... 509], a codespace which is conditionally demultiplexed as depicted in Table 5.25a, in the case stage2use was set to 1.

**Table 5.25a: Low Rate SNS stage 2 configuration (*lrshape* and *gain_bits*) and *aux* bit value decoding**

| Received value for "stopBit" b9 | Received *ind* b0 to b8 | Derived *indB* in $CB_B$ | Decoded *lrshape* value/value range | *'aux'* bit value | *'gain_bits'* | Stage 2 shape bits | Total LR SNS bits |
|---|---|---|---|---|---|---|---|
| 1 | [340 … 509] | *indB = ind-340* | 1,2,3,4,5 "LR_full"/"LR_Fix" | 1 | 3 | 18 | 30 bits |
| 0 | [0 … 169] | *indB = ind* | 0a/0b, "LR_splitLF" | 0 | 2 | 18 | 29 bits |
| 0 | [170 … 339] | *indB = ind-170* | 0a/0b, "LR_splitLF" | 1 | 2 | 18 | 29 bits |
| 0 | [340 … 509] | *indB = ind-340* | 1,2,3,4,5 "LR_full"/"LR_Fix" | 0 | 3 | 18 | 30 bits |

After parsing the table *indB* ∈ [0 ... 169] indicating an LRSNS vector in $CB_B$ , *stage2use* is set to *1* and the first stage indice *indB* is converted into an *M*-dimensional signal $st1_{indB}(n)$ according to encoder synthesis part of clause 5.3.7.3a.2.2.

Additionally the DC is removed from $st1_{indB}(n)$ to generate $st1_{indB,noDC}(n)$ according to equation (59.4 ).

### 5.4.7.2a.3 Low Rate Stage 2 SNS VQ decoding

#### 5.4.7.2a.3.1 Low Rate Stage 2 SNS-VQ index demultiplexing

The available total bit space for the dual stage low rate scale factor quantizer is 29 or 30 bits. It is used to convey four different fractional sized MPVQ-indices and four binary limited FESS-indices. The Low Rate SNS stage 2 information was multiplexed according to encoder clause 5.3.14.3.3.

Based on the determined stage 2 configuration, the gain and shape bits for the indicated shape *lrshape* are read as in the following pseudo code:

```
if( stage2inuse==1 && gain_bits==2 ) {
    lrshape    = 0;
    sns-bits   = 29;
    idxG       = read_uint(bytes, &bp_side, &mask_side, 2); /* b10, b11 */
    G_LRSNS,idxG,0   = lrsns_vq_splitLF_gainsQ12_fx[idxG];
    MPVQidxA   = read_uint(bytes, &bp_side, &mask_side, 10); /* b12 ... b21 */

    if( MPVQidxA <  N_MPVQ(N=5,K=6)/2 ) {
        LS_indB  = read_uint(bytes, &bp_side, &mask_side, 1);   /* b22 */
        MPVQidxB = read_uint(ptr, bp_side, mask_side, 6);       /* b23 ... b28 */
        K^A = 6;                                                /* indicate lrshape 0a */
    } else {
        MPVQidxA = MPVQidxA - N_MPVQ(N=5,K=6)/2;              /* range:  0 ... 31 */
        IdxTmp   =  read_uint(ptr, bp_side, mask_side, 7);  /* b22 ... b28 */
        MPVQidxA =  ( ( IdxTmp << 5 ) | MPVQidxA ):         /* bitwise-OR, range:  0 ... 2^12-1 */
        K^A =8;                                             /* indicate lrshape 0b */
    }
}
```

```
if( stage2inuse==1 && gain_bits==3 ) {
    lrshape     = 1;
    sns-bits    = 30;
    idxG        = read_uint(bytes, &bp_side, &mask_side, 3); /* b10, b11, b12 */

    G_LRSNS,idxG,1    = lrsns_vq_full_gainsQ12_fx[idxG];
    MPVQidxA    = read_uint(bytes, &bp_side, &mask_side, 17); /* b13 ... b29 */
   if( MPVQidxA >= N_MPVQ(N=15,K=5)/2 ){
        G_LRSNS,idxG,2-5  = lrsns_vq_fixenv_gainsQ12_fx[idxG];
        FESSidx     =  MPVQidxA - N_MPVQ( N=15,K=5 )/2;
        if( FESSidx >= 3*2^(2+11)){
            FESSidx     =  FESSidx - 3*2^(2+11); /* 0 ... 2^(2+9) */
            lrshape     = 5;
            envIdx      = 3;
            shiftIdx    = (FESSidx >> 9); /* 0 ... 3 */
            signsIdx    = (0x1ff & MPVQidxA); /* s1 ... s9, s9 in lsb  */
            Ns          = 10;
        } else if ( FESSidx < 1*2^(2+11)){
            FESSidx     =  FESSidx - 1*2^(2+11); /* 0 ... 2^(2+11) */
            lrshape     = 2;
            envIdx      = 0;
            shiftIdx    = (FESSidx >> 11); /* 0 ... 3 */
            Ns          = 12;
            signsIdx    = (0x7ff & FESSidx); /* s1 ... s11, s11 in lsb  */
        } else if ( FESSidx < 2*2^(2+11)){
            FESSidx     =  FESSidx - 2*2^(2+11); /* 0 ... 2^(2+11) */
            lrshape     = 3;
            envIdx      = 1;
            shiftIdx    = (FESSidx >> 11);/* 0 ... 3 */
            Ns          = 12;
            signsIdx    = (0x7ff & FESSidx); /* s1 ... s11, s11 in lsb  */
        } else {
            FESSidx     =  FESSidx - 3*2^(2+11); /* 0 ... 2^(2+11) */
            lrshape     = 4;
            envIdx      = 2;
            shiftIdx    = (FESSidx >> 11); /* 0 ... 3 */
            Ns          = 12;
            signsIdx    = (0x7ff & FESSidx);  /* s1 ... s11, s11 in lsb  */
        }
   }
}
```

Additionally for the second stage decoding , the *aux* bit derived from *b0* through *b9* is employed as the leading sign *LS_indA* for PVQ set A for a decoded PVQ shape ( *lrshape* ∈ {0a, 0b, 1}) , or as the first sign *s0* of a decoded FESS-shape ( *lrshape* ∈ { 2, 3, 4, 5 } ).

The decoded stage 2 shape indices are forwarded to a de-enumeration routine (see clauses 5.4.7.2a.3.1 and 5.4.7.2a.3.2), and then the resulting dimension *M* integer vector is unit energy normalized (see clause 5.4.7.2a.4).

### 5.4.7.2a.3.2 De-enumeration of the Low Rate SNS stage 2 shape indices

The following MPVQ and FESS de-enumeration calls are made for the demultiplexed *lrshape*.

**Table 5.25b: Low Rate SNS VQ second stage shape de-enumeration into integer vector $y_{lrshape}$ for each possible received stage 2 shape index *lrshape***

| Shape index ( *lrshape* ) | Shape name | Scale factor set A de-enumeration | Scale factor set B de-enumeration (or initialization) |
|---|---|---|---|
| 0, (0a) | *'LR_splitLF'* | MPVQdeenum (*5, $K_A$=6, &$y_{0a[1]}$, LS_indA, idxA*) | MPVQdeenum(*8, 2, z, LS_indB, idxB*); $y_{0a}(n) = z(n-6)$, *for n=6 ... 13* $y_{0a}(n) = 0$, *for n=14...15* |
| 0, (0b) | *'LR_splitLF'* | MPVQdeenum (*5, $K_A$=8, &$y_{0b[1]}$, LS_indA, idxA*) | $y_{0b}(n) = 0$, *for n=6...15* |
| 1 | *'LR_full'* | MPVQdeenum (*15, 5, &$y_{1[1]}$, LS_indA, idxA*) | $y_1(n) = 0$, *for n=15* |
| 2 | *'LR_Fix-0'* | FESSdeenum (0, *shiftIdx*, *12, &$y_{2[1]}$, signsIdx*) | n/a |
| 3 | *'LR_Fix-I'* | FESSdeenum (1, *shiftIdx*, *12, &$y_{3[1]}$, signsIdx*) | n/a |

| Shape index ( *lrshape* ) | Shape name | Scale factor set A de-enumeration | Scale factor set B de-enumeration (or initialization) |
|---|---|---|---|
| 4 | *'LR_Fix-II'* | FESSdeenum (2, *shiftIdx*, *12, &$y_{4[1]}$, signsIdx*) | n/a |
| 5 | *'LR_Fix-III'* | FESSdeenum (3, *shiftIdx*, *10, &$y_{5[1]}$, signsIdx*) | *$y_5(n) = 0$, for n=14...15* |

Where the MPVQdeenum() function is operating the same way as for the regular 38 bit SNS-VQ according to clause 5.4.7.2.3.2.

The FESSdeenum() function is providing an integer vector ***y*** by first zeroing the ***y*** vector for all *M*==16 elements, and then by extracting the integer envelope amplitudes from the trained and stored matrix `lrsns_fix_env_fx`, i.e. ***y***`[1+shiftIdx + n]` = `lrsns_fixenv_fx[envIdx][shiftIdx + n]`, for $n \in \{ 0 \ldots Ns\text{-}1 \}$, and then sequentially applying the decoded signs $s_0$ through $s_{Ns-1}$ to the non-zero values of $y[k]$, $k \in \{ 1 \ldots M\text{-}1 \}$.

### 5.4.7.2a.4 Low Rate unit energy normalization of the received integer shape vector

The de-enumerated signed integer vector $y_{lrshape}$ is normalized to a unit energy vector $x_{LRSNS,q,lrshape}$ over dimension 16 corresponding to $x_q$ in the encoder side equation (59.16) for FESS shapes and according to equation (41) for PVQ shapes.

### 5.4.7.2a.5 Reconstruction of the Quantized Low Rate SNS Scalefactors

The adjustment gain value $G_{LRSNS,idxG,lrshape}$ for gain index *idxG* is determined based on table lookup (see pseudo code in clause 5.4.7.2a.3.1).

Finally, the synthesis of the quantized low rate scale factor vector *scfQ(n)* is performed in the same way as on the encoder side, see encoder clause 5.3.7.3a.5.2.

## 5.4.7.3 SNS scale factors interpolation

The quantized scale factors $scfQ(n)$ (obtained in clause 5.4.7.2) are interpolated using:

$$
\begin{aligned}
scfQint(0) &= scfQ(0) \\
scfQint(1) &= scfQ(0) \\
scfQint(4n+2) &= scfQ(n) + \frac{1}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0 \ldots 14 \\
scfQint(4n+3) &= scfQ(n) + \frac{3}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0 \ldots 14 \\
scfQint(4n+4) &= scfQ(n) + \frac{5}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0 \ldots 14 \\
scfQint(4n+5) &= scfQ(n) + \frac{7}{8}\big(scfQ(n+1) - scfQ(n)\big) \quad for\ n = 0 \ldots 14 \\
scfQint(62) &= scfQ(15) + \frac{1}{8}\big(scfQ(15) - scfQ(14)\big) \\
scfQint(63) &= scfQ(15) + \frac{3}{8}\big(scfQ(15) - scfQ(14)\big)
\end{aligned}
\tag{117}
$$

In case, the codec is configured to operate on a number of bands $N_B < 64$, the number of scale factors need to be reduced using the following pseudo code:

```
If N_B < 32
    n4=round(abs(1-32/N_B)* N_B)
    n2 = N_B - n4

    for i=0…n4-1
        tmp(i) = 1/4 ∑_{n=4i}^{n=4i+3} scfQint(n)

    for i=0…n2-1
        tmp(n4-1+i) = 1/2 ∑_{n=4n4+2i}^{n=4n4+2i+1} scfQint(n)

else if N_B < 64
```

```
n2 = 64 -N_B;

for i=0…n2-1
    tmp(i) = 1/2 Σ_{n=2i}^{n=2i+1} scfQint(n)
for i=n2… N_B − 1
    tmp(i) = scfQint(n2 + i)
```

In case $N_B$ < 64, the the vector tmp is copied to $scfQint$. Finally, the scale factors are transformed back into linear domain using:

$$g_{SNS}(b) = 2^{scfQint(b)} \quad for\ b = 0 \ldots N_B - 1 \tag{118}$$

### 5.4.7.4 Spectral Shaping

The SNS scale factors $g_{SNS}(b)$ are applied on the TNS filtered MDCT frequency lines for each band separately in order to generate the shaped spectrum $\hat{X}(k)$ as outlined by the following code:

```
for (b=0; b<N_b; b++) {
    for (k=I_fs(b); k< I_fs(b + 1); k++) {
        X̂(k) = X̄_S(k) · g_SNS(b)
    }
}
```

## 5.4.8 Low delay MDCT synthesis

The reconstructed spectrum $\hat{X}(k)$ is transformed to the time domain by the following steps:

1) Generation of time domain aliasing buffer $\hat{t}(n)$

$$\hat{t}(n) = \sqrt{\frac{2}{N_F}} \sum_{k=0}^{N_F-1} \hat{X}(k) \cos\left[\frac{\pi}{N_F}\left(n + \frac{1}{2} + \frac{N_F}{2}\right)\left(k + \frac{1}{2}\right)\right] \quad for\ n = 0 \ldots 2N_F - 1 \tag{119}$$

2) Windowing of time-aliased buffer

$$\hat{t}(n) = w_{N_{ms_}N_F}(2N - 1 - n) \cdot \hat{t}(n) \quad for\ n = 0 \ldots 2N_F - 1 \tag{120}$$

3) Conduct overlap-add operation to get reconstructed time samples $\hat{x}(n)$

$$\hat{x}(n) = mem_ola_add(n) + \hat{t}(Z + n) \quad for\ n = 0 \ldots N_F - Z - 1 \tag{121}$$

$$\hat{x}(n) = \hat{t}(Z + n) \quad for\ n = N_F - Z \ldots N_F - 1 \tag{122}$$

$$mem_ola_add(n) = \hat{t}(N_F + Z + n) \quad for\ n = 0 \ldots N_F - Z - 1 \tag{123}$$

with $mem_ola_add(n)$ initialized to 0 before decoding the first frame.

More information is provided in clause 5.3.4 regarding any definition related to the MDCT operation.

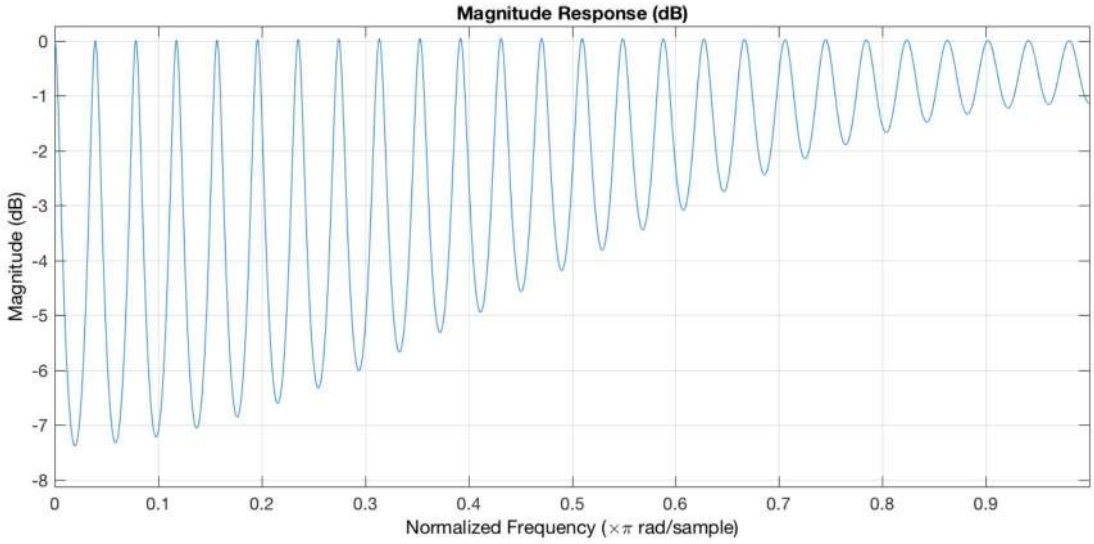

## 5.4.9 Long term postfilter

### 5.4.9.1 Overview

The decoded signal after MDCT synthesis is postfiltered in the time-domain using an IIR filter whose parameters depend on the LTPF bitstream data "pitch_index" and "ltpf_active". As the filter coefficients are a pre-defined set, the result of the IIR filter is always stable. To avoid any discontinuity when the parameters change from one frame to the next, a transition mechanism is applied.

For simplicity, audio samples of past frames are accessed by negative indexing, e.g. $x(-1)$ is the most recent sample of the signal $x$ in the previous frame. Note that in practice, a buffer mechanism would have to be implemented.

The LTPF sharpens the harmonic structure of the signal by attenuating the quantization noise in the spectral valleys. An example of an LTPF frequency response for a speech signal is given in Figure 5.11.

NOTE: The harmonic structure is sharpened by attenuation of the spectral valleys and quantization noise is perceptually optimized.

**Figure 5.11: Example of LTPF frequency response for a speech signal**

### 5.4.9.2 Transition handling

The transition corresponds to the first 2,5 ms of the current frame ($n = 0 \ldots \frac{f_s \cdot f_{scal}}{400} - 1$). For $N_{ms}$=1,25, the transition spans over two subsequent frames covering also 2,5 ms. In this case, the first half of the transition fading gain vector $n$ is applied in the current frame while the second half is applied in the subsequent frame.

Note that mem_ ltpf_active corresponds to the value of ltpf_active in the previous frame (it is initialized to zero before the first frame is processed), $\hat{x}(n)$ is the filter input signal (i.e. the decoded signal after MDCT synthesis), $\widehat{x_{ltpf}}(n)$ is the filter output signal, the filter parameters $c_{num}$, $c_{den}$, $p_{int}$ and $p_{fr}$ are given below, and $c_{num}^{mem}$, $c_{den}^{mem}$, $p_{int}^{mem}$ and $p_{fr}^{mem}$. Where *mem* always denotes the value from the previous frame.

Five different cases are considered:

1) First case: ltpf_active = 0 and mem_ ltpf_active = 0

$$\widehat{x_{ltpf}}(n) = \hat{x}(n) \tag{124}$$

2) Second case: ltpf_active = 1 and mem_ ltpf_active = 0

$$\widehat{x_{ltpf}}(n) \leftarrow \hat{x}(n) - \frac{n}{norm}\left[\sum_{k=0}^{L_{num}} c_{num}(k)\hat{x}(n-k) - \sum_{k=0}^{L_{den}} c_{den}(k, p_{fr})\widehat{x_{ltpf}}\left(n - p_{int} + \frac{L_{den}}{2} - k\right)\right] \tag{125}$$

3) Third case: ltpf_active = 0 and mem_ ltpf_active = 1

$$\widehat{x_{ltpf}}(n) \leftarrow \hat{x}(n) - \left(1 - \frac{n}{norm}\right)\left[\sum_{k=0}^{L_{num}} c_{num}^{mem}(k)\hat{x}(n-k) - \sum_{k=0}^{L_{den}} c_{den}^{mem}(k, p_{fr}^{mem})\widehat{x_{ltpf}}\left(n - p_{int}^{mem} + \frac{L_{den}}{2} - k\right)\right] \tag{126}$$

with $c_{num}^{mem}$, $c_{den}^{mem}$, $p_{int}^{mem}$ and $p_{fr}^{mem}$ are the filter parameters computed in the previous frame:

4) Fourth case: ltpf_active = 1 and mem_ltpf_active = 1 and $p_{int} = p_{int}^{mem}$ and $p_{fr} = p_{fr}^{mem}$

$$\widehat{x_{ltpf}}(n) \leftarrow \hat{x}(n) - \sum_{k=0}^{L_{num}} c_{num}(k)\hat{x}(n-k) + \sum_{k=0}^{L_{den}} c_{den}(k, p_{fr})\widehat{x_{ltpf}}\left(n - p_{int} + \frac{L_{den}}{2} - k\right) \tag{127}$$

5) Fifth case: ltpf_active = 1 and mem_ltpf_active = 1 and ($p_{int} \neq p_{int}^{mem}$ or $p_{fr} \neq p_{fr}^{mem}$)

$$\widehat{x_{ltpf}}'(n) \leftarrow \hat{x}(n) - \left(1 - \frac{n}{norm}\right)\left[\sum_{k=0}^{L_{num}} c_{num}^{mem}(k)\hat{x}(n-k) - \sum_{k=0}^{L_{den}} c_{den}^{mem}\left(k, p_{fr}^{mem}\right)\widehat{x_{ltpf}}'\left(n - p_{int}^{mem} + \frac{L_{den}}{2} - k\right)\right] \quad (128)$$

$$\widehat{x_{ltpf}}(n) \leftarrow \widehat{x_{ltpf}}'(n) - \frac{n}{norm}\left[\sum_{k=0}^{L_{num}} c_{num}(k)\widehat{x_{ltpf}}'(n-k) - \sum_{k=0}^{L_{den}} c_{den}\left(k, p_{fr}\right)\widehat{x_{ltpf}}\left(n - p_{int} + \frac{L_{den}}{2} - k\right)\right] \quad (129)$$

where $norm = \frac{N_F}{4} \cdot \frac{10}{N_{ms}}$.

### 5.4.9.3 Remaining of the frame

The remainder of the frame corresponds to the remaining samples of the current frame ($n = \frac{f_s \cdot f_{scal}}{400} \ldots N_F - 1$).

Two different cases are considered:

1) First case: ltpf_active = 0

$$\widehat{x_{ltpf}}(n) = \hat{x}(n) \quad (130)$$

2) Second case: ltpf_active = 1

$$\widehat{x_{ltpf}}(n) \leftarrow \hat{x}(n) - \sum_{k=0}^{L_{num}} c_{num}(k)\hat{x}(n-k) + \sum_{k=0}^{L_{den}} c_{den}\left(k, p_{fr}\right)\widehat{x_{ltpf}}\left(n - p_{int} + \frac{L_{den}}{2} - k\right) \quad (131)$$

with $\hat{x}(n)$ is the filter input signal (i.e. the decoded signal after MDCT synthesis), $\widehat{x_{ltpf}}(n)$ is the filter output signal and $n = 0 \ldots N_F - 1$.

The integer part $p_{int}$ and the fractional part $p_{fr}$ of the LTPF pitch-lag are computed as follows. First the pitch-lag at 12,8 kHz (see clause 5.3.10) is recovered using:

$$\text{pitch_int} = \begin{cases} \text{pitch_index} - 283 & \text{if pitch_index} \geq 440 \\ \left\lfloor \frac{\text{pitch_index}}{2} \right\rfloor - 63 & \text{if } 440 > \text{pitch_index} \geq 380 \\ \left\lfloor \frac{\text{pitch_index}}{4} \right\rfloor + 32 & \text{if } 380 > \text{pitch_index} \end{cases} \quad (132)$$

$$\text{pitch_fr} = \begin{cases} 0 & \text{if pitch_index} \geq 440 \\ 2 \cdot \text{pitch_index} - 4 \cdot \text{pitch_int} - 252 & \text{if } 440 > \text{pitch_index} \geq 380 \\ \text{pitch_index} - 4 \cdot \text{pitch_int} + 128 & \text{if } 380 > \text{pitch_index} \end{cases} \quad (133)$$

$$\text{pitch} = \text{pitch_int} + \frac{\text{pitch_fr}}{4} \quad (134)$$

The pitch-lag is then scaled to the output sampling rate $f_s$ and converted to integer and fractional parts using:

$$\text{pitch}_{f_s} = \text{pitch} \cdot \frac{8\,000 \cdot ceil\left(\frac{f_s}{8\,000}\right)}{12\,800} \quad (135)$$

$$p_{up} = \text{nint}\left(\text{pitch}_{f_s} \cdot 4\right) \quad (136)$$

$$p_{int} = \left\lfloor \frac{p_{up}}{4} \right\rfloor \quad (137)$$

$$p_{fr} = p_{up} - 4 \cdot p_{int} \quad (138)$$

The filter coefficients $c_{num}(k)$ and $c_{den}(k, p_{fr})$ are computed as follows:

$$c_{num}(k) = 0{,}85 \cdot gain_{ltpf} \cdot \text{tab_ltpf_num_fs[gain_ind][}k\text{]} \quad for\ k = 0 \ldots L_{num} \tag{139}$$

$$c_{den}(k, p_{fr}) = gain_{ltpf} \cdot \text{tab_ltpf_den_fs}[p_{fr}][k] \quad for\ k = 0 \ldots L_{den} \tag{140}$$

with:

$$L_{den} = \max\left(4, \frac{f_s}{4\,000}\right) \tag{141}$$

$$L_{num} = L_{den} - 2 \tag{142}$$

and $gain_{ltpf}$ and $gain_{ind}$ are obtained according to:

```
/* correction table for smaller frame sizes */
if N_ms == 1,25
    t_nbits = nbits * 8 * 0.42;
else N_ms == 2,5
    t_nbits = nbits * 4 * (1 - 0.4);
else if N_ms== 5
    t_nbits = nbits * 2 - 160;
else if N_ms== 7,5
    t_nbits = round(nbits * 10 / 7.5);
else if N_ms== 10
    t_nbits = nbits
end

/* tuning lookup */
fs_idx = min(4,(f_s/8000-1));
if (t_nbits < 320 + fs_idx*80)
{
    gain_ltpf = 0.4;
    gain_ltpf_max = 0.6;
    gain_ind = 0;
}
else if (t_nbits < 400 + fs_idx*80)
{
    gain_ltpf = 0.35;
    gain_ltpf_max = 0.55;
    gain_ind = 1;
}
else if (t_nbits < 480 + fs_idx*80)
{
    gain_ltpf = 0.3;
    gain_ltpf_max = 0.5;
    gain_ind = 2;
}
else if (t_nbits < 560 + fs_idx*80)
{
    gain_ltpf = 0.25;
    gain_ltpf_max = 0.45;
    gain_ind = 3;
}
else
{
    gain_ltpf = 0;
}
```

The tables for $\text{tab_ltpf_num_fs[gain_ind]}[k]$ and $\text{tab_ltpf_den_fs}[p_{fr}][k]$ are given in clause 5.9.5, Table 5.42.

### 5.4.9.4 Adaptive gain for LTPF

For $N_{ms}$=1,25, adaptive gain is used for LTPF. The LTPF gain is increased in steps if the pitch remains unchanged for more than 12,5 ms, i.e. 10 frames each of 1,25 ms. When the pitch changes or the LTPF is deactivated, the gain is decreased slowly in steps. Any fluctuations in the pitch lag are also corrected for signals which exhibit stable pitch.

In adaptive gain, a constant of 0,98 is used instead of 0,85 in equation (139) in clause 5.4.9.3. Also, adaptive gain updates are made only in the frames where the first part of the transition is applied as described in clause 5.4.9.2.

Adaptive gain uses four Boolean control variables:

1) $ltpf_active$ indicates if LTPF shall be applied in the current frame as described in clause 5.4.9.1.

2) $mem_ltpf_active$ indicates if LTPF was applied in the previous frame as described in clause 5.4.9.1.

3) $pitch_changed$ indicates if pitch lag has changed in the current frame.

4) $pitch_was_stable$ indicates if pitch lag was stable for the past frames.

A counter is used to keep track of the stability of the pitch lag. It is updated as in Table 5.25c.

**Table 5.25c: LTPF adaptive gain pitch stability counter update**

| Control Variables | | | | Pitch stability counter update |
|---|---|---|---|---|
| ltpf_active | mem_ltpf_active | pitch_changed | pitch_was_stable | |
| true | X | false | X | increment by one update interval |
| Any combination of values other than the above | | | | reset |

The value of the update interval is 2,5 ms. If the value of the counter is greater than or equal to 12,5 ms, then pitch is assumed to be stable and $pitch_was_stable$ is set to true.

Pitch stability is also decided based on normalized correlations computed over the current frame $\hat{x}(n)$ for the coded pitch lag in the current frame and the pitch lag used by LTPF in the previous frame. Normalized correlation is computed using equation (87) in clause 5.3.10.5, where $L = N_F$ and $T = p_{int}$. The control variable $pitch_was_stable$ is set to $true$ if the normalized correlation corresponding to the pitch lag used by LTPF in the previous frame is greater than the normalized correlation corresponding to the coded pitch lag in the current frame. These computations are done only if the variable $pitch_changed$ is $true$ and the pitch lags are non-zero.

When LTPF becomes active after being inactive in the previous frame(s), the gain value indicated by the variable $gain_ltpf$ in clause 5.4.9.3 is used. In the subsequent frames, based on the values of the control variables, it is updated in small steps as shown in Table 5.25d.

**Table 5.25d: LTPF adaptive gain update**

| Control Variables | | | | Gain update |
|---|---|---|---|---|
| ltpf_active | mem_ltpf_active | pitch_changed | pitch_was_stable | |
| true | X | false | X | increment by 0,01 |
| true | X | true | false | decrement by $gain_ltpf_max/20$ |
| false | true | true | false | decrement by 0,01 |
| false | false | X | false | set to 0 |
| Any combination of values other than the above | | | | use $gain_ltpf$ from previous frame |

The gain is allowed to reach a maximum value indicated by the variable $gain_ltpf_max$ given in clause 5.4.9.3. In case the gain gets lower than the initial value of $gain_ltpf$ after decrement, the gain is set to 0.

Based on the values of the control variables, pitch lag is corrected as in Table 5.25e.

**Table 5.25e: LTPF adaptive gain control pitch lag correction**

| Control Variables | | | | LTPF Pitch lag |
|---|---|---|---|---|
| ltpf_active | mem_ltpf_active | pitch_changed | pitch_was_stable | |
| true | X | true | false | use $p_{int}$ and $p_{fr}$ from the pitch_index in the current frame |
| Any combination of values other than the above | | | | use $p_{int}$ and $p_{fr}$ from the LTPF applied in the previous frame |

### 5.4.10 Output signal scaling and rounding

The LTPF output signal $\widehat{x_{ltpf}}(n)$ for all samples with index $n \in [0, N_F - 1]$ is clipped to upper integer value range:

$$\widehat{x_{clip}}(n) = \begin{cases} 2^{15} - 1, & \widehat{x_{ltpf}}(n) > 2^{15} - 1 \\ -2^{15}, & \widehat{x_{ltpf}}(n) < -2^{15} \\ \widehat{x_{ltpf}}(n), & otherwise \end{cases} \quad (143)$$

Afterwards, the signal $\widehat{x_{clip}}(n)$ is scaled to the proper range using:

$$x_o(n) = nint\left(\widehat{x_{clip}}(n) \cdot 2^{-15+s-1}\right) \quad (144)$$

The output signal $x_o(n)$ is in the PCM integer format using $s$ bits per sample.

## 5.5 Frame structure

The frame structure of the codec consists of four parts, i.e.:

- Side information containing static bits about the configuration of the frame data. This data block starts at the end of the frame and is read backwards. It includes information about audio bandwidth, global gain, noise level, TNS activity, LTPF, SNS data, the index of the last non-zero spectral line and parts of the quantized spectrum. An exact bit stream definition can be found in clause 5.4.2.3.
- A dynamic data block which is arithmetically coded and contains TNS and fractional parts of the quantized spectrum. This block is read from the beginning of the frame towards the end. The decoding of this block is described in clause 5.4.2.4.
- A dynamic data block with signs and least significant bits part of the quantized spectrum. This block is read backwards from the end of the static side information bits. The decoding of this dynamic data block is described in clause 5.4.2.7.
- The residual data is located between the two dynamic data blocks and contains refinements of the quantized spectrum. It is read backwards starting immediately after the last encoded side information dynamic data block with spectrum signs and spectrum LSBs. The residual data is described according to clause 5.4.2.8.

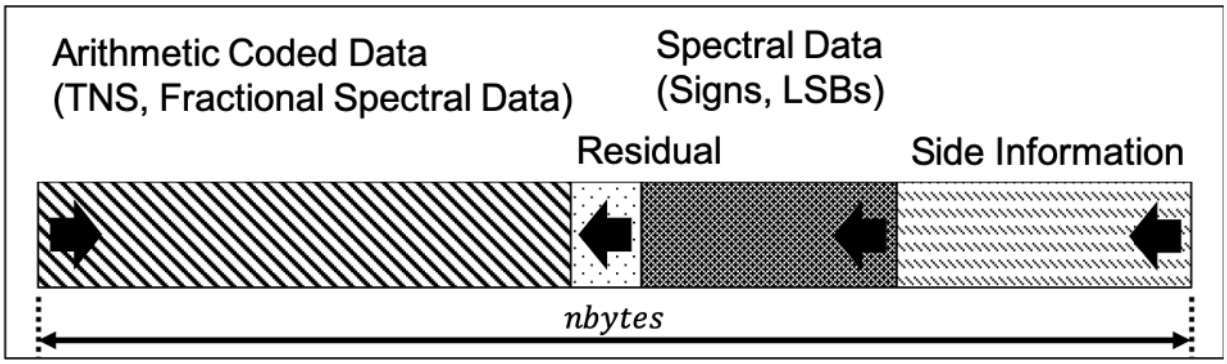

**Figure 5.12: Frame structure**

## 5.6 Error concealment

### 5.6.1 General consideration

The purpose of the Packet Loss Concealment (PLC) is to conceal the effect of unavailable or corrupted frame data for decoding. The overall composite PLC algorithm is described in clause 5.6.3 and when this composite algorithm shall be applied for the LC3plus, is described in clause 5.6.2.

The frame loss concealment procedure comprises three sub-concealment methods for various signal types. Best possible codec performance in error-prone situations with frame losses is obtained through selecting the most suitable method, as described in clause 5.6.3. The packet loss sub-concealment methods are:

- MDCT frame repetition with sign scrambling, clause 5.6.3.2
- Time domain concealment, clause 5.6.3.3
- Frequency domain concealment (Phase ECU), clause 5.6.3.4

The overall composite PLC algorithm including all three sub-concealment methods and the corresponding PLC method selection as described in clause 5.6.3 shall be used to guarantee a certain service quality.

## 5.6.2 PLC trigger

The decoder shall apply a packet loss concealment algorithm for the following three events:

a) The decoder receives an externally determined Bad Frame Indicator (BFI=1) flag signalling a lost frame or the presence of any detected bit error in the received compressed frame to the decoder.

b) The special decoder mode for PLC is detected as described in clause 5.4.2.4.

c) The decoder detects a bit error marked with BEC_detect=1 in clause 5.4.2.

## 5.6.3 PLC method selection and method application

### 5.6.3.1 Method selection

The selection of the PLC method is performed only in the first lost frame after a good frame and remains unchanged in subsequently lost frames. The criteria for the method selection are:

- Pitch value $T_c$:

$$T_c = \begin{cases} 0, & \text{pitch_present} = 0 \\ \text{pitch_int}, & \text{pitch_present} = 1 \end{cases} \quad (145)$$

  where $\text{pitch}_{\text{present}}$ and pitch_int are the LTPF parameters calculated in clauses 5.3.10.6 and 5.3.10.7 from the last good frame.

- Cross-correlation value $xcorr$:

$$xcorr = \frac{\sum_{k=0}^{N-1} x(k) \cdot x(k - T_c)}{\sqrt{(\sum_{k=0}^{N-1} x(k) \cdot x(k)) \cdot (\sum_{k=0}^{N-1} x(k - T_c) \cdot x(k - T_c))}} \quad (146)$$

  where $x(k), k = 0 \ldots N - 1$ are the last decoded time samples, and

$$N = \begin{cases} f_s \cdot \frac{64}{12\,800}, & T_c < f_s \cdot \frac{64}{12\,800} \\ T_c, & f_s \cdot \frac{64}{12\,800} \leq T_c \leq \frac{f_s}{100} \\ \frac{f_s}{100}, & \mathrm{T_c} > \frac{f_s}{100} \end{cases} \quad (147)$$

- Spectral centroid $sc$:

$$sc = \frac{f_s}{48\,000} \cdot \frac{\sum_{k=0}^{15} g_d(k) \cdot \frac{bands(k)}{N_F}}{\sum_{k=0}^{15} g_d(k) \cdot (I_{fs}(4k+4) - I_{fs}(4k))} \tag{148}$$

where:

$$bands(k) = \sum_{b=I_{PLC}(4k)+1}^{I_{PLC}(4k+4)} b \quad for\ k = 0 \ldots 15 \tag{149}$$

and

$$g_d(k) = \frac{2^{scfQ_{-1}(k)}}{10^{k \cdot \frac{g_{tilt}}{150}}} \quad for\ k = 0 \ldots 15 \tag{150}$$

where $scfQ_{-1}(k)$ is the scalefactor vector of the last good frame, $g_{tilt}$ is the tilt factor given in Table 5.7 and $I_{PLC}$ is $I_{f_s}$ if $I_{f_s} = 64$ and otherwise as described in the following pseudo code:

```
If N_b < 32
     I_PLC(0) = 0
     j = 32 – N_b

     for (i=N_b-1; i>=j; i--)
          I_PLC((i+j)*2+2) = I_fs(i + 1)
          I_PLC((i+j)*2+1) = I_fs(i + 1)

     for (i=j-1; i>=0; i--)
          I_PLC(i*4+4) = I_fs(i + 1)
          I_PLC(i*4+3) = I_fs(i + 1)
          I_PLC(i*4+2) = I_fs(i + 1)
          I_PLC(i*4+1) = I_fs(i + 1)

else if N_B < 64
     I_PLC(0) = 0
     j = 64 – N_b

     for (i=N_b-1; i>=j; i--)
          I_PLC(i+j+1) = I_fs(i + 1)

     for (i=j-1; i>=0; i--)
          I_PLC(i*2+2) = I_fs(i + 1)
          I_PLC(i*2+1) = I_fs(i + 1).
```

The decision logic of the different PLC methods uses the criteria shown above and the value $class$:

$$class = \frac{7\,640}{32\,768} xcorr\ - sc\ - \frac{5\,112}{32\,768} \tag{151}$$

The decision is done as follows:

- MDCT frame repetition with sign scrambling is selected if $T_c = 0$
- Time domain concealment is selected if $T_c > 0$ and either $class > 0$ or $N_{ms} < 10$
- Frequency domain concealment (Phase ECU) is selected if $T_c > 0$ and $class \leq 0$ and $N_{ms} = 10$

If the sample frequency fs is equal to 24 kHz or is greater or equal to 44,1 kHz, the PLC method decision is stored for the last 2 seconds in $stat(m, k)$, where $k$ is the frame index and $m$ is the PLC method index defined by:

- 3: stores decision of $time$ domain concealment
- 4: stores decision of MDCT frame repetition with sign scrambling

The frame in $stat(m,k)$ is marked as 1 for the selected PLC method index and 0 for the remaining method. For each $stat(m)$, a $longterm_counter(m)$ is calculated by $longterm_counter(m) = \sum_{k=0}^{kmax} stat(m,k)$, where $kmax$ is maximum frame index representing 2 seconds.

For every frame, the buffers shall be updated and long-term counter variables shall be calculated only when *numberOfGoodFrames* > *resetClassifierThreshold* (i.e. no updates for concealed frames and the first *resetClassifierThreshold* subsequent good frames. In addition to that, an overall_counter variable shall be updated as follows:

```
overall_counter = min(overall_counter+1, 0.5*kmax);
```

In case of a lost frame and the sample frequency being 24 kHz or greater or equal to 44,1 kHz and $N_{ms} > 1{,}25$, a PLC fadeout parameter *plc_fadeout_type* shall be calculated based on the *longterm_counter* variables:

```
if (fs_idx == 2 || fs_idx >= 4)
{
     if ((longterm_counter(3) < thresh_tdc_cnt){
         PlcAdvSetup->plc_fadeout_type = 1;
     }
     else if (longterm_counter(4) < thresh_ns_cnt){
         PlcAdvSetup->plc_fadeout_type = 1;
     }
     else if ((longterm_counter(3) + longterm_counter(4) < thresh_tdc_ns_cnt){
         PlcAdvSetup->plc_fadeout_type = 1;
     }
     else {
         PlcAdvSetup->plc_fadeout_type = 0;
     }

} else {
    plc_fadeout_type = 0;
}

if (overall_counter < (0.5*kmax))
{
    plc_fadeout_type = 0;
}
```

Where *thresh_tdc_cnt*, *thresh_ns_cnt* and *thresh_tdc_ns_cnt* are defined in Table 5.25f depending on the frame duration.

**Table 5.25f: Thresholds for PLC longterm counter variables**

| | $N_{ms}$ | | | |
|---|---|---|---|---|
| | **10** | **7,5** | **5** | **2,5** |
| *thresh_tdc_cnt* | 9 | 7 | 22 | 20 |
| *thresh_ns_cnt* | 7 | 7 | 15 | 21 |
| *thresh_tdc_ns_cnt* | 73 | 87 | 141 | 278 |

If the relative pitch change of the last valid frame exceeds a threshold of 0,36, the pitch is considered as unstable and the $plc_fadeout_type$ is set to 2, which controls the fadeout (see clause 5.6.3.3.7). In each valid frame, the *rel_pitch_change* is calculated from the old pitch value of the previous frame and the new pitch value of the current frame:

$$rel_pitch_change = \frac{|pitch_old - pitch_new|}{\max(pitch_old, 1)} \quad (151.1)$$

with $pitch_{new} = p_{int} + \frac{p_{fr}}{4}$, $pitch_{old} = p_{int}^{mem} + \frac{p_{fr}^{mem}}{4}$ and $p_{int}, p_{fr}, p_{int}^{mem}, p_{fr}^{mem}$ defined in clause 5.4.9.2.

The rel_pitch_change shall be only considered for high-resolution mode at frame durations of 2,5 and 5 ms.

### 5.6.3.2 MDCT frame repetition with sign scrambling

The intermediate spectrum of the concealed frame $\widehat{X'}(k)$ is derived by sign scrambling of the last received shaped spectrum $\hat{X}_{lastGood}(k)$ of clause 5.4.8:

```
for k=0.. N_F − 1
  plc_seed = (16831 + plc_seed*12821) & 0xFFFF;
  if plc_seed < 0
    if pitch_present == 0 || plc_seed < randThreshold || plc_fadeout_type != 0
      X'(k) = −X̂_lastGood(k);
    else
      X'(k) = X̂_lastGood(k);
```

with the initial value of `plc_seed=24 607` (this value is initialized only once at decoder startup and is not reset after the appearance of an error-free frame), where pitch_present is the LTPF parameter calculated in clause 5.3.10.6 from the last good frame, and

$$\text{randThreshold} = -32\,768 \cdot \text{linFuncStartStop} \tag{152}$$

where linFuncStartStop is determined as follows:

```
plc_duration_inFrames = plc_end_inFrames - plc_start_inFrames;
x = max(plc_start_inFrames, (min (nbLostCmpt, plc_end_inFrames)));
m = -1 / plc_duration_inFrames;
b = - plc_end_inFrames;
linFuncStartStop = m * (x + b);
```

where:

$$plc_end_inFrames = \left\lfloor f_{10ms} \cdot \frac{10}{N_{ms}} \right\rfloor \tag{153}$$

with:

$$f_{10ms} = \frac{PLC4_TRANSIT_END_IN_MS}{10} \tag{154}$$

where the default value of PLC4_TRANSIT_END_IN_MS = 60 with the minimum value of 20, nbLostCmpt being the number of consecutive concealed frames, and

$$\text{plc_start_inFrames} = \begin{cases} 1, & \text{if pitch_present} = 0 \\ \left\lfloor \frac{20}{N_{ms}} \right\rfloor, & \text{otherwise} \end{cases} \tag{154.1}$$

where pitch_present is the LTPF parameter calculated in clause 5.3.10.6 from the last good frame. To prevent rapid high energy increase, the spectrum is high pass filtered with $\widehat{X'}(0) \leftarrow \widehat{X'}(0) \cdot 0{,}2$ and $\widehat{X'}(1) \leftarrow \widehat{X'}(1) \cdot 0{,}5$. The spectrum $\widehat{X'}(k)$ is damped adaptively based on the two damping factors:

$$slow' = 0{,}8 + 0{,}2 \cdot \theta \tag{155}$$

and

$$fast' = 0{,}3 + 0{,}2 \cdot \theta \tag{156}$$

where $\theta$ is the stability factor computed as follows:

$$\theta = 1{,}25 - \frac{1}{25}\sum_{k=0}^{15}\left(scfQ_{-1}(k) - scfQ_{-2}(k)\right)^2 \tag{157}$$

where the stability factor $\theta$ is truncated to $0 \leq \theta \leq 1$, with larger values of $\theta$ corresponding to more stable signals. This limits energy and spectral envelope fluctuations. If there are no two adjacent scale factor vectors present, $\theta$ is set to 0,8. The two factors $slow'$ and $fast'$ are calculated if nbLostFrames = 1 and stay for consecutive lost frames. Based on these and the number of consecutive lost frames, the two damping factors $slow''_k$ and $fast''_k$ are calculated as follows:

$$slow''_k = \begin{cases} 0, & if\ nbLostCmpt_loc > f_{10ms} \\ slow' \cdot 0{,}5, & else\ if\ nbLostCmpt_loc > 2 \\ slow', & else \end{cases} \tag{158}$$

and

$$fast''_k = \begin{cases} 0, & if\ nbLostCmpt_loc > f_{10ms} \\ fast' \cdot 0{,}5, & else\ if\ nbLostCmpt_loc > 2 \\ fast', & else \end{cases} \tag{159}$$

where:

$$nbLostCmpt_loc = \left\lfloor \frac{(nbLostCmpt - 1) + \frac{10}{N_{ms}}}{\frac{10}{N_{ms}}} \right\rfloor \tag{160}$$

Finally, the two damping factors $slow_k$ and $fast_k$ are calculated as follows:

$$slow_k = \begin{cases} \sqrt[8]{slow''_k}, & for\ N_{ms} = 1{,}25 \\ \sqrt[4]{slow''_k}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{slow''_k}, & for\ N_{ms} = 5 \\ \sqrt[4]{(slow''_k)^3}, & for\ N_{ms} = 7{,}5 \\ slow''_k, & otherwise \end{cases} \tag{161}$$

and

$$fast_k = \begin{cases} \sqrt[8]{fast''_k}, & for\ N_{ms} = 1{,}25 \\ \sqrt[4]{fast''_k}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{fast''_k}, & for\ N_{ms} = 5 \\ \sqrt[4]{(fast''_k)^3}, & for\ N_{ms} = 7{,}5 \\ fast''_k, & otherwise \end{cases} \tag{162}$$

For plc_fadeout_type == 0, the corresponding cumulative attenuation factors $\text{cum_fading_slow}_k$ and $\text{cum_fading_fast}_k$ are calculated as follows:

$$\text{cum_fading_slow}_\text{k} = \text{cum_fading_slow}_{\text{k}-1} \cdot slow_k \tag{163}$$

and

$$\text{cum_fading_fast}_\text{k} = \text{cum_fading_slow}_{\text{k}-1} \cdot fast_k \tag{164}$$

where $\text{cum_fading_slow}_{k-1}$ and $\text{cum_fading_fast}_{k-1}$ are the cumulative attenuation factors of the previous frame or 1 if nbLostFrames = 1.

For plc_fadeout_type != 0 the cumulative attenuation factor $\text{cum_fading_slow}_k$ is calculated:

$$\text{cum_fading_slow}_\text{k} = \begin{cases} \text{cum_fading_slow}_{\text{k}-1}, & \text{if nbLostCmpt} < 4 \cdot \frac{10}{\text{N}_\text{ms}} \\ \text{cum_fading_slow}_{\text{k}-1} \cdot 0{,}9, & \text{else if nbLostCmpt} < 8 \cdot \frac{10}{\text{N}_\text{ms}} \\ \text{cum_fading_slow}_{\text{k}-1} \cdot 0{,}85, & \text{else} \end{cases} \tag{164.1}$$

Finally, the damping is processed as follows:

```
ad_ThreshFac_start = 10;
ad_ThreshFac_end   = 1.2;
ad_threshFac = (ad_ThreshFac_start - ad_ThreshFac_end) * linFuncStartStop + ad_ThreshFac_end;
frame_energy = mean(X̂'(k)(0.. N_F − 1).^2);
energThreshold = ad_threshFac * frame_energy;
for k=0.. N_F − 1
    if (X̂'(k)^2) < energThreshold || plc_fadeout_type != 0
        m = cum_fading_slow;
        n = 0;
    else
        m = cum_fading_fast;
        n = (cum_fading_slow-cum_fading_fast) * sqrt(energThreshold) * sign(X̂'(k));
    end

    X̂(k) = m * X̂'(k) + n;
end
```

to form the spectrum $\hat{X}(k)$ for clause 5.4.8.

If the Long Term Postfilter was active in the last good frame, the filter is also applied on the synthesized concealed time signal as described in clause 5.6.4 with $\alpha = slow_k$.

### 5.6.3.3 Time domain concealment

#### 5.6.3.3.1 Overview

The time domain concealment method is a pitch-based PLC technique operating in the time domain. It is best suited for signals with a dominant harmonic structure. The general description of the algorithm is as follow: the synthesized signal of the last decoded frames is inverse filtered with the Linear Prediction (LP) filter as describes in clause 5.6.3.3.2 to obtain the periodic signal as described in clause 5.6.3.3.3. The random signal is generated by a random generator with approximately uniform distribution as described in clause 5.6.3.3.4. The two excitation signals are summed up to form the total excitation signal as described in clause 5.6.3.3.5, which is adaptively faded out with the attenuation factor described in clause 5.6.3.3.7 and finally filtered with the LP filter to obtain the synthesized concealed time signal. If LTPF was active in the last good frame, the LTPF is also applied on the synthesized concealed time signal as described in clause 5.6.4. To get a proper overlap with the first good frame after a lost frame, the time domain alias cancelation signal is generated as described in clause 5.6.3.3.6.

#### 5.6.3.3.2 LPC parameter calculation

The time domain concealment method is operating in the excitation domain of the time domain, therefore an LP filter is calculated in the first lost frame after a good frame and remains for the subsequently lost frames. The order of the LP filter is:

$$M = \begin{cases} 8, & N_F \leq 20 \\ 16, & else \end{cases} \tag{165}$$

The autocorrelation function $r(k)$ is derived from the energies per band $E_B(b)$ (see clause 5.3.4.4), but with:

$$N_b = \begin{cases} 60, & f_s \neq 32\,000 \ and \ f_s \neq 96\,000 \text{ and } N_{ms} = 7{,}5 \\ 60, & f_s = 48\,000 \ and \ N_{ms} = 2{,}5 \\ 40, & f_s = 24\,000 \ and \ N_{ms} = 5 \\ \min(N_F, 80), & else \end{cases} \tag{166}$$

and

$$I_{f_s}(b) = \frac{N_F}{N_b} b, \qquad for\ b = 0 \ldots N_b \tag{167}$$

Afterwards $E_B(b)$ is pre-emphasized using:

$$E_P(b) = E_B(b) \cdot \left(1 + \mu^2 - 2\mu \cdot \cos\left(\frac{\pi(b + 0{,}5)}{N_b}\right)\right), \qquad for\ b = 0 \ldots N_B - 1 \tag{168}$$

with $\mu$ given in Table 5.26.

**Table 5.26: Pre-emphasis factor table**

| $f_s$ (Hz) | $\mu$ |
|---|---|
| 8 000 | 0,62 |
| 16 000 | 0,72 |
| 24 000 | 0,82 |
| ≥ 32 000 | 0,92 |

The vector $E_P(b)$ is transformed to the time domain using an inverse odd DFT:

$$r_{Pre}(n) = Re\left(\sum_{b=0}^{N_b-1} E_P(b) \cdot e^{j\frac{\pi \cdot n}{N_b}\left(b+\frac{1}{2}\right)}\right), \quad for\ n = 0 \dots N_B - 1 \tag{169}$$

In case $r_{Pre}(0) = 0$, set $r_{Pre}(0) = 1$ and $r_{Pre}(1 \dots N_b - 1) = 0$. The first M samples are extracted into the vector $r_L = r_{Pre}(0 \dots M - 1)$. The autocorrelation function is lag windowed using:

$$r_{Lag}(k) = \begin{cases} r_L(k) \cdot 1{,}0001, & for\ k = 0 \\ r_L(k) \cdot exp\left[-\frac{1}{2}\left(\frac{120\pi k}{f_s}\right)^2\right], & for\ k = 1 \dots M \end{cases} \tag{170}$$

The Levinson-Durbin recursion described in clause 5.3.9.2 is used with $r_{Lag}(k)$ to obtain LPC coefficients $a_c(k), k = 0 \dots M$ for the concealed frame.

### 5.6.3.3.3 Construction of the periodic part of the excitation

#### 5.6.3.3.3.1 Processing in the first lost frame

The last $M + T_c + \frac{N_F}{2}$ decoded time samples are first pre-emphasized with the pre-emphasis factor from Table 5.26 using the filter:

$$H_{pre-emph}(z) = 1 - \mu z^{-1} \tag{171}$$

to obtain the signal $x_{pre}(k), k = 0 \dots M + T_c + \frac{N_F}{2}$, where $T_c$ is the pitch-lag value pitch_int or pitch_int + 1 if pitch_fr > 0, where the values pitch_int and pitch_fr are the pitch-lag values transmitted in the last good bitstream, as described in clause 5.4.9.3.

The pre-emphasized signal, $x_{pre}(k)$, is further filtered with the inverse LP filter, $a_c(k)$, calculated in clause 5.6.3.3.2 to obtain the prior excitation signal:

$$exc_p\left(k - T_c - \frac{N_F}{2}\right) = x_{pre}(k + M) + \sum_{i=1}^{M} a_c(i) \cdot x_{pre}(k + M - i), \quad for\ k = 0 \dots T_c + \frac{N_F}{2} - 1 \tag{172}$$

If the stability factor $\theta$ from clause 5.6.3.2 is smaller than one, the pitch period to construct the periodic excitation signal are inductively defined by:

$$harmonicBuf(k) \leftarrow \sum_{i=0}^{10} exc_p(k - T_c - 5 + i) \cdot h_{LP}(i), \quad for\ k = 0 \dots T_c - 1 \tag{173}$$

where $h_{LP}$ constitutes an 11-tap linear phase FIR filter whose coefficients are given in Table 5.27. Otherwise, they are defined by:

$$harmonicBuf(k) = exc_p(k - T_c), \quad for\ k = 0 \dots T_c - 1 \tag{174}$$

$$[void] \tag{175}$$

**Table 5.27: Low pass FIR filter coefficients**

| $f_s$ (Hz) | $\mathbf{h_{LP}}$ |
|---|---|
| 8 000 to 16 000 | {0,0053, 0,0000, -0,0440, 0,0000, 0,2637, 0,5500, 0,2637, 0,0000, -0,0440, 0,0000, 0,0053} |
| > 16 000 | {-0,0053, -0,0037, -0,0140, 0,0180, 0,2668, 0,4991, 0,2668, 0,0180, -0,0140, -0,0037, -0,0053} |

The gain of pitch $g_p$ is calculated as follows:

$$g_p' = \frac{\sum_{k=0}^{\frac{N_F}{2}-1} x_{pre}(M+k) \cdot x_{pre}(M+T_c+k)}{\sum_{k=0}^{\frac{N_F}{2}-1} x_{pre}(M+k)^2} \tag{176}$$

If pitch_fr $= 0$ then $g_p = g_p'$. Otherwise, $g_p''$ is calculated as follows:

$$g_p'' = \frac{\sum_{k=0}^{\frac{N_F}{2}-1} x_{pre}(M+k+1) \cdot x_{pre}(M+T_c+k)}{\sum_{k=0}^{\frac{N_F}{2}-1} x_{pre}(M+k+1)^2} \tag{177}$$

and $g_p = \max(g_p', g_p'')$. If $g_p'' > g_p'$ then $T_c = T_c - 1$ for further processing.

Finally, $g_p$ is truncated to $0 \leq g_p \leq 1$. Furthermore, if $\mathrm{nbLostCmpt} = 1$:

- $\hat{\alpha}_{-1} = 1$
- $\beta = 0$.

#### 5.6.3.3.3.2 Processing in each lost frame

The periodic part of the excitation is constructed based on the content of the $harmonicBuf$ as described in the following pseudo code:

```
harmonicBufPtr = harmonicBuf + (((nbLostCmpt - 1) * N_F) mod T_c) ;
for ( k = 0; k < T_c + N_F/2; k++ ) {
  if (harmonicBufPtr - harmonicBuf  >= T_c) {
    harmonicBufPtr = harmonicBuf;
  }
    exc_p[k]  = *harmonicBufPtr++;
}
```

The formed periodic excitation, $exc_p(k)$ is attenuated as follows:

$$\widehat{exc_p}(k) = \left(1 + \frac{k}{N_F - 1}(\hat{\alpha} - \hat{\alpha}_{-1})\right) \cdot exc_p(k), \quad for\ k = 0 \ldots N_F - 1 \tag{178}$$

where the attenuation factor:

$$\hat{\alpha} = \alpha \tag{179}$$

$\alpha$ is given in clause 5.6.3.3.7.

Furthermore, if $\mathrm{nbLostCmpt} > 1$:

- $\hat{\alpha}_{-1}$ is $\hat{\alpha}$ of the previous frame.
- $g_p$ is set to $\hat{\alpha}_{-1}$.

### 5.6.3.3.4 Construction of the random part of the excitation

The random part of the excitation is generated with a simple random generator with approximately uniform distribution as follows:

$$exc_{n,FB}(k) = (16\,831 + exc_{n,FB}(k-1) \cdot 12\,821)\ \&\ \mathrm{0xFFFF}, \quad for\ k = 0 \ldots N_F + 10 \tag{180}$$

where $exc_{n,FB}(-1)$ is initialized with 24 607 for the very first frame concealed with this method. For further frames, $exc_{n,FB}(N_F + 10)$ is stored and used as next $exc_{n,FB}(-1)$.

To shift the noise towards higher frequencies, the excitation signal is high pass filtered with an 11-tap linear phase FIR filter given in Table 5.28 to get:

$$\boldsymbol{exc_{n,HP}(k) = \sum_{i=0}^{10} exc_{n,FB}(k+i) \cdot h_{HP}(i), \quad for\ k = 0 \ldots N_F} \tag{181}$$

**Table 5.28: High pass FIR filter coefficients**

| $f_s$ (Hz) | $\mathbf{h_{HP}}$ |
|---|---|
| 8 000 to 16 000 | {0, -0,0205, -0,0651, -0,1256, -0,1792, 0,8028, -0,1792, -0,1256, -0,0651, -0,0205, 0} |
| > 16 000 | {-0,0517, -0,0587, -0,0820, -0,1024, -0,1164, 0,8786, -0,1164, -0,1024, -0,0820, -0,0587, -0,0517} |

To ensure that the noise fades to full band noise, the random part of the excitation $exc_n(k)$ is composed via an interpolation between the full band $exc_{n,FB}(k)$ and the high pass filtered version $exc_{n,HP}(k)$ as:

$$exc_n(k) = \beta \cdot exc_{n,FB}(k+5) + (1-\beta) \cdot exc_{n,HP}(k), \quad for\ k = 0 \ldots N_F - 1 \tag{182}$$

where $\beta = 0$ for the first lost frame after a good frame, and

$$\beta = (1 - \hat{\alpha}) \cdot t \tag{183}$$

with:

$$t = \frac{nbLostCmpt_loc}{(nbLostCmpt_loc + 30)} \tag{183.1}$$

for the second and further consecutive frame losses, where $nbLostCmpt_loc$ is calculated in equation (160), and

$$\hat{\alpha} = \alpha \tag{184}$$

The fading speed is dependent on the attenuation factor $\alpha$ calculated in clause 5.6.3.3.7. For adjusting the noise level, the gain of noise, $g'_n$, is calculated in the first lost frame after a good frame as:

$$g'_n = \sqrt{\frac{\sum_{k=0}^{\frac{N_F}{2}-1} \left( exc_p\left(k - \frac{N_F}{2}\right) - \widehat{g_p} \cdot exc_p\left(k - T_c - \frac{N_F}{2}\right)\right)^2}{\frac{N_F}{2}}} \tag{185}$$

where:

$$\widehat{g_p} = g_p \tag{186}$$

and $g_p$ is the gain of pitch calculated in clause 5.6.3.3.3. To prevent high energy increase at $f_s = 8\ 000\ Hz$, $g'_n$ is controlled by:

$$g'_n \leftarrow \begin{cases} \sqrt{\frac{\sum_{k=0}^{\frac{N_F}{2}-1} \left( exc_p\left(k - \frac{N_F}{2}\right)\right)^2}{\frac{N_F}{2}}}, & if\ g'_n > \sqrt{\frac{\sum_{k=0}^{\frac{N_F}{2}-1} \left( exc_p\left(k - \frac{N_F}{2}\right)\right)^2}{\frac{N_F}{2}}} \\ g'_n, & else \end{cases} \tag{187}$$

If $T_c = \text{pitch_int}$ after clause 5.6.3.3.3, then $g_n = g'_n$. Otherwise, a second gain of noise, $g''_n$, is calculated as done in equation (185) and equation (187), but with $T_c = \text{pitch_int}$. Following, $g_n = \min(g'_n, g''_n)$.

The composed random excitation $exc_n(k)$ is attenuated as follows:

$$\widehat{exc_n}(k) = \left(1 + \frac{k}{N_F - 1}\left(\frac{\hat{\alpha}}{\hat{\alpha}_{-1}} - 1\right)\right) \cdot g_n \cdot n_n \cdot exc_n(k), \qquad for\ k = 0 \ldots N_F - 1 \tag{188}$$

where $\hat{\alpha}_{-1} = 1$ if nbLostCmpt = 1 and $\hat{\alpha}_{-1}$ is $\hat{\alpha}$ of the previous frame if nbLostCmpt > 1 and the normalization factor $n_n$ is:

$$n_n = (1{,}1 - 0{,}75 g_p) \cdot \frac{1}{\sqrt{\frac{exc_n(k) \cdot exc_n(k)}{N_F}}}, \quad for\ k = 0 \ldots N_F - 1 \tag{189}$$

to obtain $\widehat{exc_n}(k)$. The noise gain, $g_n$, is calculated only in the first lost frame after a good frame and is stored as $g_{n,next} = g_n \cdot \alpha$ for the next consecutive frame loss, where $g_{n,next}$ is the gain of noise of the next consecutive frame loss.

### 5.6.3.3.5 Construction of the total excitation, synthesis and post-processing

The random excitation, $\widehat{exc_n}(k)$, is added to the periodic excitation, $\widehat{exc_p}(k)$, to form the total excitation signal $exc_t(k)$. The synthesized signal $synth(k)$ for the concealed frame is obtained by filtering the total excitation with the LP filter, $a_c(k)$, from clause 5.6.3.3.2 and post-processed with the de-emphasis filter, which is the inverse filter from equation (171).

If $nbLostCmpt_loc = f_{10ms}$ and $nbLostCmpt_loc_{-1} < nbLostCmpt_loc$, with $nbLostCmpt_loc$ from equation (160), $nbLostCmpt_loc_{-1}$ is $nbLostCmpt_loc$ from the previous frame and $f_{10ms}$ from equation (154), then $synth(k)$ is faded out to zero as follows:

$$synth(k) \leftarrow \left(1 - \frac{k}{N_F}\right) \cdot\ synth(k), \quad for\ k = 0 \ldots N_F - 1 \tag{190}$$

where for $plc_fadeout_type \geq 1$, $PLC4_TRANSIT_END_IN_MS$ in equation (154) is set to 200.

For further frame losses the signal and $\alpha$ is set to zero.

### 5.6.3.3.6 Time domain alias cancelation

To get a proper overlap add in the case the next frame is a good frame, the time domain alias cancelation part $x_{TDAC}(k)$ has to be generated. For that, $N_F - Z$ additional samples are created the same way as described above to obtain the signal $x(k)\ for\ k = 0 \ldots 2N_F - Z$. On that, the time domain alias cancelation part is created by the following steps:

1) Zero padding the synthesized time domain buffer $x(k)$

$$\hat{x}(k) = \begin{cases} 0, & 0 \leq k < Z \\ x(k - Z), & Z \leq k < 2N_F \end{cases} \tag{191}$$

2) Windowing $\hat{x}(k)$ with the MDCT window $w_N(k)$

$$\widehat{x_w}(k) = w_N(k) \cdot \hat{x}(k), \qquad 0 \leq k < 2N_F \tag{192}$$

3) Reshaping from $2N_F$ to $N_F$

$$y(k) = \begin{cases} -\widehat{x_w}\left(\frac{3N_F}{2} + k\right) - \widehat{x_w}\left(\frac{3N_F}{2} - 1 - k\right), & 0 \leq k < \frac{N_F}{2} \\ \widehat{x_w}\left(-\frac{N_F}{2} + k\right) - \widehat{x_w}\left(\frac{3N_F}{2} - 1 - k\right), & \frac{N_F}{2} \leq k < N_F \end{cases} \tag{193}$$

4) Reshaping from $N_F$ to $2N_F$

$$\hat{y}(k) = \begin{cases} y\left(\frac{N_F}{2} + k\right), & 0 \le k < \frac{N_F}{2} \\ -y\left(\frac{3N_F}{2} - 1 - k\right), & \frac{N_F}{2} \le k < N_F \\ -y\left(\frac{3N_F}{2} - 1 - k\right), & N_F \le k < \frac{3N_F}{2} \\ -y\left(-\frac{3N_F}{2} + k\right), & \frac{3N_F}{2} \le k < 2N_F \end{cases} \quad (194)$$

5) Windowing $\hat{y}(k)$ with the flipped MDCT window $w_N(k)$

$$x_{TDAC}(k) = w_N(2N_F - 1 - k) \cdot \hat{y}(k), \qquad 0 \le k < 2N_F \quad (195)$$

### 5.6.3.3.7 Handling of multiple frame losses

In general, the constructed signal fades out towards zero for multiple frame losses. The fade out speed is controlled by an attenuation factor $\alpha$ which is dependent on the previous attenuation factor $\alpha_{-1}$, the gain of pitch $g_p$ calculated on the last correctly received frame and updated in every consecutive frame loss, the number of consecutive erased frames $nbLostCmpt$, and the stability factor $\theta$, as calculated in clause 5.6.3.2. The attenuation factor is calculated as follows:

$nbLostCmpt_{loc} = \left\lfloor \frac{nbLostCmpt + \frac{10}{N_{ms}} - 1}{\frac{10}{N_{ms}}} \right\rfloor$

$type2fadeoutselector = 10$

```
if (plc_fadeout_type == 2 && (N_ms == 5 || N_ms == 2.5){
    if (type2fadeoutselector·2·10/N_ms >= nbLostCmpt){
        if (nbLostCmpt <= 3·10/N_ms){
            α = 0.95^((nbLostCmpt + 10/N_ms − 1)·N_ms/10)
        }
        else {
            n_shift = (nbLostCmpt − 3 × 10/N_ms)·5/N_ms
            α = 0.7^((n_shift + 10/N_ms − 1)·N_ms/10)
        }
    }
    else {
        α = 0.5^((nbLostCmpt + 10/N_ms − 1)·N_ms/10)
    }

} else {
   nbLostCmpt_mod = (nbLostCmpt − 1) & 0x0007
   if (N_ms == 10 || (N_ms == 7.5 && ( nbLostCmpt_mod ! = 1 || nbLostCmpt_mod ! = 5 ) || (N_ms ==
   5 && (nbLostCmpt_mod & 0x0001 == 0)) || (N_ms == 2.5 && nbLostCmpt_mod& 0x0003 == 0) || (N_ms ==
   1.25 && nbLostCmpt_mod == 0))

     if (nbLostCmpt_loc == 1)
       α = √g_p
       if (α > 0.98)
         α = 0.98
       else if (α < 0.925)
         α = 0.925
     else if (nbLostCmpt_loc == 2)
       α = (0.63 + 0.35 θ)·g_p
       if α < 0.919
         α = 0.919;
     else
       α = (0.652 + 0.328 θ)·g_p
   else
     α = α_−1

   if (nbLostCmpt_loc > 3)
     α = α·0.5^(N_ms/10)
   if (nbLostCmpt_loc > 5)
     g_p = α
}
```

### 5.6.3.4 Frequency domain concealment (Phase ECU)

#### 5.6.3.4.1 Phase ECU overview

One of the advanced ECU modes is the Phase ECU and it is used for both speech signals and general audio signals. It operates by performing a time evolution of decoded signal in the frequency domain. This technique assumes that the lost frame can be represented by a limited number of sinusoidal components that are identified in a time signal. These sinusoidal components are time evolved to replace the lost frame, the calculated frame substitute is then processed using the MDCT-related TDA and ITDA steps.

The Phase ECU operation employs in total a 26 ms duration time domain signal for calculating the replacement signal in case of lost frames, the most recent (rightmost) 16 ms part of the decoded signal, with length $L_{prot}$ samples is called the prototype signal $x_{right}$.

For the first lost frame there are three separate steps: a transient analysis, fine spectral analysis and frame reconstruction. In the first step, the transient analysis, the spectral shape and the frame energy are used to detect transients in sub bands and calculate modification parameters, which is described in clause 5.6.3.4.3. The second step, the fine spectral analysis, identifies the sinusoidal components which is described in clause 5.6.3.4.4. In the final third step, the frame reconstruction, the sinusoids are time evolved and are converted back to the time domain and that is described in clause 5.6.3.4.5. In case of consecutive lost frames, that is during error bursts, processing consists of control parameter updates made by the transient analysis described in clause 5.6.3.4.3 and frame reconstruction as described in clause 5.6.3.4.5.

#### 5.6.3.4.2 Spectral Shape

For the transient analysis the Phase ECU uses a MDCT based spectral shape and a frame energy to estimate how the signal evolves over time. The spectral shape is calculated based on the decoded MDCT coefficients. The transient analysis spectral shape consists of sub-band energy estimates where the number of sub-bands depends on the sampling frequency as seen in Table 5.29.

**Table 5.29: Phase ECU Number of bins table**

| $f_s$ (Hz) | $N_{grp}$ |
|---|---|
| 8 000 | 4 |
| 16 000 | 5 |
| 24 000 | 6 |
| 32 000 | 7 |
| 44 100, 48 000 | 8 |

Table 5.30 shows how MDCT coefficients are divided among the sub-bands. The table entries show start coefficients of each sub-band.

**Table 5.30: Phase ECU MDCT band start coefficients**

| Frame duration | Vector name | MDCT coefficient number | MDCT resolution |
|---|---|---|---|
| 10 ms | $grp_start_coef(k)$ | {4, 14, 24, 44, 84, 164, 244, 324, 404} | 50 Hz |

The sub-band based spectral shapes are normalized to the range $[0,1]$ so first the total magnitude of the MDCT coefficients are calculated as:

$$shape_tot_{right} = \sum_{n=0}^{\min(399,\, N_{MDCT}-1)} q_d_{right}(n)^2 \quad (196)$$

$$shape_tot_{left} = \sum_{n=0}^{\min(399,\, N_{MDCT}-1)} q_d_{left}(n)^2 \quad (197)$$

Two normalized spectral shapes for the sub-bands are calculated as:

$$shape_{right}(k) = \frac{1}{shape_tot_{right}} \sum_{n=grp_start_coef(k)}^{grp_start_coef(k+1)-1} q_d_{right}(n)^2, \qquad 0 \le k < N_{grp} \tag{198}$$

which forms the normalized spectral shape for corresponding to the last encoded frame (analysed over the most recent 16,25 ms on the encoder side), and

$$shape_{left}(k) = \frac{1}{shape_tot_{left}} \sum_{n=grp_start_coef(k)}^{grp_start_coef(k+1)-1} q_d_{left}(n)^2, \qquad 0 \le k < N_{grp} \tag{199}$$

which forms the normalized spectral shape corresponding to the frame preceding the last encoded frame.

Two frame energies are calculated as:

$$E_w_{right} = \sum_{n=0}^{L_{prot}-1} \left(w_{whr}(k) \cdot x_{right}(k)\right)^2 \tag{200}$$

$$E_w_{left} = \sum_{n=0}^{L_{prot}-1} \left(w_{whr}(k) \cdot x_{left}(k)\right)^2 \tag{201}$$

Where $w_{whr}$ is the Phase ECU spectral analysis window, $x_{right}$ consists of the most recent $L_{prot}$ samples of the total 26 ms time domain signal, and $x_{left}$ corresponds to the first $L_{prot}$ samples of the 26 ms signal.

#### 5.6.3.4.3 Transient analysis

The transient analysis employs the spectral shapes and the frame energies to analyse how the sub-band energies are evolving over the last 26 ms in each band $k$ and to build a long-term spectral average $x_{avg}$ for each band $k$, an average that is used to adjust the scaling of the FFT synthesis bins during extended burst errors.

**Table 5.31: Phase ECU FFT Sub-Bands start bin numbers**

| Vector name | FFT bin numbers (at 250 Hz resolution) |
|---|---|
| grp_start_bin(k) | {1, 3, 5, 9, 17, 33, 49, 65, 81, 97} |

The spectral shapes and frame energies are used to generate the approximations of sub-band energies corresponding to the last 26 ms. The first corresponds to the frame before the last frame as:

$$E_{left}(k) = \mu \cdot shape_{left}(k) \cdot E_w_{left}, \qquad 0 \le k < N_{grp} \tag{202}$$

The second corresponds to the last frame as:

$$E_{right}(k) = \mu \cdot shape_{right}(k) \cdot E_w_{right}, \qquad 0 \le k < N_{grp} \tag{203}$$

Where $\mu$ is a constant that depends on the sampling frequency and handles the conversion of the MDCT based spectral shape to an approximation of an FFT based spectral analysis and are shown in Table 5.32.

**Table 5.32: Phase ECU MDCT coefficient to FFT bin spectral shape conversion factor $\mu$**

| $f_s$ (Hz) | $\mu$ *(factor)* |
|---|---|
| 8 000 | 1,9906 |
| 16 000 | 4,0445 |
| 24 000 | 6,0980 |
| 32 000 | 8,1533 |
| 44 100, 48 000 | 12,2603 |

These are used to calculate the ratio of energies for the two positions as:

$$G_{tran}(k) = \frac{E_{right}(k)}{E_{left}(k)}, \qquad 0 \le k < N_{grp} \tag{204}$$

This forms the basis of a frequency selective transient detection for each frequency band $k$. The gain in compared with an upper and lower threshold that represent onset and offset detection respectively. If $G_{tran}(k) > 10$ or $G_{tran}(k) < 0{,}1$ is fulfilled the band $k$ contains a transient and $T_{tran}(k)$ is set to 1. The gains $G_{mag}(k)$ are set to 1. If a band has a transient, the gain $G_{mag}(k)$ is updated to:

$$G_{mag}(k) = \min\left(1, \sqrt{G_{tran}(k)}\right), \qquad 0 \le k < N_{grp} \tag{205}$$

The gains $G_{mag}(k)$ for the first lost frame are saved into $G'_{mag}(k)$.

To better handle burst conditions, magnitude and phase modification factors are updated. The first part in the magnitude modification is a low-resolution spectral shape, and is calculated according to the following:

$$\bar{E}_{tran}(k) = \sqrt{\frac{1}{2} \cdot \frac{E_{left}(k) + E_{right}(k)}{grp_start_bin(k+1) - grp_start_bin(k)}}, \qquad 0 \le k < N_{grp} \tag{206}$$

Here $\bar{E}_{tran}(k)$ now forms a low-resolution bin amplitude estimate in band $k$. It is used for a generating a spectrally shaped additive noise signal to which the substitution signal is pulled towards in case of burst frame losses.

The second part in the magnitude modification is the adjustment of the gain $G_{mag}(k)$ which is updated band wise according to:

$$G_{mag}(k) = G'_{mag}(k) \cdot 10^{-G_{att}/20}, \qquad 0 \le k < N_{grp} \tag{207}$$

where:

$$\begin{gathered} K_{att} = 0{,}30103 \\ N_{att} = \begin{cases} 3 & , plc_fadeout_type = 0 \\ 5 & , plc_fadeout_type = 1 \end{cases} \\ L_{att} = \begin{cases} 2 & , plc_fadeout_type = 0 \\ 9 & , plc_fadeout_type = 1 \end{cases} \end{gathered} \tag{208}$$

$$\begin{cases} G_{att} = 0, & N_{lost} \le N_{att} \\ G_{att} = (N_{lost} - N_{att}) \cdot K_{att}, & N_{att} < N_{lost} \le N_{att} + L_{att} \\ G_{att} = L_{att} \cdot K_{att} + (N_{lost} - N_{att}) \cdot 6{,}0206, & N_{lost} > N_{att} + L_{att} \end{cases} \tag{209}$$

Here $N_{lost}$ is the number of consecutive lost frames.

The attenuation factors $\alpha(k)$ and $\beta(k)$ are updated as:

$$\begin{gathered} \alpha(k) = G_{mag}(k) \\ \beta(k) = \beta_{mute} \cdot \sqrt{1 - \alpha^2(k)}, \end{gathered} \qquad 0 \le k < N_{grp} \tag{210}$$

Through variable $\alpha(k)$ the concealment method is modified by selectively adjusting the magnitude of the substitution frame spectrum base on the frequency domain transient detector status $G_{tran}(k)$.

The scaling factor $\beta(k)$ is used to scale the spectrally shaped additive noise signal such that, except for the incorporated gradual muting behaviour through factor $\beta_{mute}$, it compensates for the energy loss caused by the attenuation with factor $\alpha(k)$.

For $k = 5$, $\beta(k)$ is further adjusted as $\beta(k) = \beta(k) \cdot 0{,}5$ and for $k > 6$ then $\beta(k) = \beta(k) \cdot 0{,}1$. This superimposes a low-pass characteristic on the additive noise signal, which avoids unpleasant high frequency noise in the substitution signals.

Further at the end of a longer burst of lost frames the additive noise scaling factor $\beta_{mute}$ is adjusted for every frame as follows:

$$\beta_{\text{mute}} = \begin{cases} \beta_{mute} \cdot 0{,}5, & N_{lost} > 5 \ \cap \ plc_fadeout_type = 0 \\ \beta_{mute} \cdot 0{,}5, & N_{lost} > 14 \ \cap \ plc_fadeout_type = 1 \\ \beta_{\text{mute}}, & \text{otherwise} \end{cases} \quad (210.1)$$

### 5.6.3.4.4 Fine Spectral analysis

For the first lost frame the prototype frame signal, $x_{right}$ , is used for a fine high-resolution spectral analysis:

$$X_F(k) = \text{FFT}\left(w_{hr}(n) \cdot x_{right}(n)\right), \qquad 0 \le n < L_{prot}, 0 \le k \le N_{FFT} \quad (211)$$

Where $X_F(k)$ is complex valued, $w_{hr}(n)$ is a hamming-rectangular window, and $L_{prot}$ is the length of the FFT input which depends on the sampling frequency used as shown in Table 5.33.

**Table 5.33: Phase ECU Prototype length and Number of FFT bins**

| $f_s$ (Hz) | $L_{prot}$ (samples) | $N_{FFT}$ (complex valued bins) |
|---|---|---|
| 8 000 | 128 | 64 |
| 16 000 | 256 | 128 |
| 24 000 | 384 | 192 |
| 32 000 | 512 | 256 |
| 44 100, 48 000 | 768 | 384 |

The shape of the window is defined as a periodic hamming window:

$$w_{hr}(n) = \begin{cases} 0{,}56 + 0{,}46 \cdot \cos\left(\dfrac{\pi \cdot n}{L_h + 1}\right), & 0 \le n < L_h \\ 1{,}00, & L_h \le n < L - L_h \\ 0{,}56 + 0{,}46 \cdot \cos\left(\dfrac{\pi \cdot \left(n - L_{prot} + 2 \cdot L_h\right)}{L_h + 1}\right), & L - L_h \le n < L_{prot} \end{cases} \quad (212)$$

And $L_h$ is the length of the hamming part which depends on the sampling frequency $f_s$ as shown in Table 5.34.

**Table 5.34: Phase ECU Length of hamming part in HammRect window**

| $f_s$ (Hz) | $L_h$ (samples) |
|---|---|
| 8 000 | 12 |
| 16 000 | 24 |
| 24 000 | 36 |
| 32 000 | 48 |
| 44 100, 48 000 | 96 |

In case of a burst error consecutive frames are based on the same prototype signal analysis so the complex valued spectrum $X_F(k)$ is saved. To locate the peaks in the spectrum the magnitude spectrum is first calculated $|X_F(k)|$ and this is sent to the peak locator method. It returns the found number of peaks $N_{peaks}$ and the peak locations $k_p(j), j = 0, \dots, N_{peaks} - 1$. These peak locations only hold peak locations with the frequency resolution of the FFT bin distance, which is insufficient for high quality phase evolution. To increase the frequency resolution the magnitude spectrum and peak locations are sent to a refinement method that use both real valued and complex valued interpolation. After the interpolation the peak locations are fractional peak locations $k'_p(j), j = 0, \dots, N_{peaks} - 1$.

These fractional peak locations (sinusoidal frequencies) form the basis of the sinusoidal mode used for the reconstructions of the lost audio frames described further during frame reconstruction in clause 5.6.3.4.5.

### 5.6.3.4.4a Noise only analysis and modification

If the peak locator results in many peaks, i.e. $N_{peaks} > 14$, then the complete signal $X_F$ is assumed to not contain sinusoids and is evolved as a noise only signal by setting the number of peak locations to zero (i.e. $N_{peaks} = 0$), and thus evolving the spectrum as a single valley noise only signal with random phases per spectral bin.

#### 5.6.3.4.4b Single sinusoid analysis and modification

Before evolving the identified spectral peaks, the $N_{peaks}$ integer peak locations in $k_p$, the corresponding fine spectral analysis amplitudes $|X_F(k_{bin})| = x_{abs}(k_{bin})$, the longer term spectral band amplitude estimates $\bar{E}_{tran}(k_{band})$ are analysed improve the fidelity when reconstructing single pure relatively high SNR sinusoid signals.

An initial hypothesis of a single sinusoidal is initialized based on the peak locator result as follows:

$$single_tone_present = \begin{cases} false, & N_{peaks} = 0 \ \cup \ N_{peaks} > 2 \\ true, & 1 \leq N_{peaks} \leq 2 \end{cases} \quad (212.1)$$

If the condition $single_tone_present$ is $true$ a secondary analysis whether to keep the $X_F(k)$ valley amplitudes or mute the $X_F(k)$ valley bins in is made as follows:

- The register $npt_detect$ is initialized zero (implying an initial assumption of a pure sinusoid), the register is then used to store the evaluation results of three different non-pure-tone(*npt*) criteria:
- The assumed single sinusoid main lobe width is analysed using $k_p$, $N_{peaks}$ and $x_{abs}(k_{bin})$ and the valley bins amplitudes will be kept if the main lobe is too wide to represent a single pure sinusoid: For an established too wide main lobe a value 0x01 is added to $npt_detect$.
- The dynamic range of the assumed sinusoid is analysed in the bins surrounding the assume sinusoid bin, using: $k_p$, $N_{peaks}$ and $\boldsymbol{x_{abs}(k_{bin})}$. The valley bins amplitudes will be kept if the amplitudes variation in an 812,5 Hz wide band centered on the assumed main lobe is less than 24 dB and thus not likely to represent a single pure sinusoid. If low dynamics is observed near the main lobe, a value 0x02 is added to $npt_detect$.
- The spectral amplitude envelope is analysed in terms of an expected dual sided band-wise tapering-off for a pure sinusoid, using $k_p$, $N_{peaks}$, the fine resolution amplitudes $x_{abs}(k_{bin})$, the coarse longer term resolution amplitudes in $\bar{E}_{tran}(k_{band})$ and band-border sensitivity weights $scATH(k_{band})$ for each band border, where the *scATH* weights are based on the Absolute Threshold for hearing Curve (ATH), and are thus taking into account the increased subjective sensitivity in the central region compared to the low and high frequency regions. If the band-wise weighted accumulated amplitude increases from low to high on the high frequency side of the central band is larger than 6,0 dB, a value 0x10 is added to $npt_detect$. If the band-wise weighted accumulated amplitude increases from high to low on the low frequency side of the central band is larger than 6,0 dB, a value 0x20 is added to $npt_detect$. If the band-wise weighted accumulated amplitude increases on both sides of the central band is larger than 4,5 dB, a value 0x40 is added to $npt_detect$.

**Table 5.34a: Phase ECU Sinusoidal analysis ATH-weights**

| Vector name | ATH-weights per band border |
|---|---|
| $scATH(k_{band})$ | {0,455, 0,931, 0,973, 1,000, 0,908, 0,776, 0,500} |

Subsequently after the analysis steps a resulting all zero $npt_detect$ register is used in the frame reconstruction to turn off the noise generation in the assumed spectral valley bins, this deactivation reduces a granular evolution noise which may otherwise arise due to the Phase ECU approximation of a pure sinusoid being represented using a limited number of spectral bins around a main central lobe. On the other hand, when $npt_detect$ is non-zero the signal is assumed to be a single sinusoid with a significant background noise envelope and it will be evolved without losing energy in the non-sinusoidal valley regions of the overall spectrum.

#### 5.6.3.4.5 Frame reconstruction

For the reconstruction the fractional peak locations from the spectral analysis is used to create a time evolved reconstruction frame. This is done by phase adjusting the identified peaks $k'_p$ of size $N_{peaks}$ to fit the time location of the reconstructed frame.

While the exact time evolution of the sinusoids of the windowed prototype signal frame would require complex superposition of frequency-shifted, phase-evolved and sampled instances of the spectrum of the used window function, Phase ECU operates with an approximation of the window function spectrum such that it comprises only a region around its main lobe. With this approximation the substitution frame spectrum is composed of strictly non-overlapping portions of the approximated window function spectrum and hence the time evolution of the sinusoids of the windowed prototype signal frame reduces to phase shifting the sinusoidal components of the prototype spectrum in $\delta$-regions around each spectral peak $j$ by an amount $\theta(j)$.

Note that this amount $\theta(j)$ merely depends on the respective sinusoidal frequency (fractional peak location) $k'_p(j), j = 0, \dots, N_{peaks} - 1$ and the time shift between the lost frame and the prototype signal frame. This is expressed in equation (213). The phase shift is calculated as:

$$\theta(j) = 2\pi \cdot \frac{k'_p(j)}{L_{prot}} \cdot \left(2 \cdot L - \frac{2 \cdot L - L_{prot}}{2} - \frac{L}{2 + k_{offs}} - K\right), \qquad 0 \le j < N_{peak} \tag{213}$$

where $k_{offs}$ is the offset in number of samples since the last good frame. $k_{offs}$ is a variable incremented by $L$ for each lost frame, and $L$ equals the length of the frame.

**Table 5.35: Phase ECU frame size table**

| $f_s$ (Hz) | L (samples) |
|---|---|
| 8 000 | 80 |
| 16 000 | 160 |
| 24 000 | 240 |
| 32 000 | 320 |
| 44 100, 48 000 | 480 |

Next the spectrum around each spectral peak $j$ is evolved and random noise component related to burst loss handling is added:

$$X'_F(k) = \alpha(\mathrm{k}) \cdot X_F(k) \cdot e^{i \cdot \theta(j)} + \beta(\mathrm{k}) \cdot \bar{G}_{tran}(k) \cdot e^{i \cdot 2 * \pi \cdot rand(k)} \tag{214}$$

Where $k = j - \delta_1, \dots, j + \delta_2$, $rand(k)$ is a random number between 0 and 1.

$$\begin{aligned} \delta_1 &= \min\left(5, \frac{k_p(j) - k_p(j-1) - 1}{2}\right) \\ \delta_2 &= \min\left(5, \frac{k_p(j+1) - k_p(j) - 1}{2}\right), \end{aligned} \qquad 0 \le j < N_{peak} \tag{215}$$

The remaining spectral coefficients which have not been evolved are processed in similar manner but with a randomized phase. In the special case of a pure single sinusoid is identified and the register $npt_detect$ only contains zeroes, the amplitudes of the valley spectral coefficients are zeroed.

For clarity it is to be noted that the first additive term in equation (214) relates to phase shifting the sinusoidal components of the prototype spectrum. In addition, for longer bursts the magnitude of the prototype signal frame spectral coefficients is attenuated with the scaling factor $\alpha(j)$. The second additive term in equation (214) modifies the substitution frame spectral coefficients by an additive noise component, where the magnitude of the additive noise component corresponds to the scaled coefficients of the low-resolution magnitude spectrum of the previous good frame, $\bar{G}_{tran}$,. The scaling factor $\beta(j)$ is chosen such that, except for the incorporated gradual muting behaviour, it compensates for the energy loss caused by the attenuation with factor $\alpha(j)$. This is an aspect of the long-term muting behaviour which is outlined in clause 5.6.3.4.3.

The reconstructed signal $x_{ph}(n)$ is produced by applying the Inverse FFT to the evolved spectrum $X'_F$ and normalizing the resulting time domain signal using the $whr(n)$ window according to equation (216).

$$x_{ph}(n) = \mathrm{IFFT}\frac{\left(X'_F(k)\right)}{whr(n)}, \qquad 0 \le n < L_{prot}, 0 \le k \le N_{FFT} \tag{216}$$

The reconstructed signal $x_{ph}(n)$ of length $L_{prot}$ is then extended in two directions to achieve the same length $(2 \cdot L)$ as the normal MDCT window. The extended signal $x'_{ph}$ is constructed as follows, a first 2 ms part is copied from a position 3,75 ms from the end of the prototype signal $x_{right}(n)$, a second 1,75 ms part is created by overlap adding the end 1,75 ms of the prototype signal $x_{right}$(n), with the initial 1,75 ms part of the reconstructed signal $x_{ph}(n)$. A third 12,5 ms part is copied from the remaining reconstructed signal $x_{ph}(n)$. Finally, a fourth 3,75 ms part, after the copied reconstructed signal consists of zeroes. The total composite extended signal $x'_{ph}(n)$ of length $(2 \cdot L)$ is then MDCT windowed and time domain aliased in a manner corresponding normal encoding described in clause 5.3.4. The resulting windowed and the time-domain aliased signal is then inverse time domain aliased, windowed and overlap-added with the previous frame in a manner corresponding to normal decoding steps described in clause 5.4.8.

### 5.6.4 PLC operation related to LTPF

If mem_ltpf_active=1 in the concealed frame, then ltpf_active is set to 1 if the concealment method is as defined in clause 5.6.3.2 or clause 5.6.3.3. Therefore, the Long Term Postfilter is applied on the synthesized time domain signal as described in clause 5.4.9, but with $\hat{x}(n)$ being the decoded signal after MDCT synthesis of clause 5.6.3.2 or the synthesized time domain signal of clause 5.6.3.3.5, pitch_int and pitch_fr are pitch_int and pitch_fr of the last good frame, and:

$$\text{gain_ltpf} = \text{gain_ltpf_last} \cdot \alpha \tag{217}$$

where gain_ltpf_last is the LTPF gain of the previous frame and $\alpha$ is the attenuation factor from clause 5.6.3.2 or clause 5.6.3.3.7 respectively.

If mem_ltpf_active=1 and the concealment method is as defined in clause 5.6.3.4 in a first concealed frame, then ltpf_active is set to 0, this enables the fade-out path of the LTPF filter from clause 5.4.9.2.

For consecutive lost frames, the pitch values pitch_int and pitch_fr which are used for the LTPF stay fixed.

## 5.7 External rate adaptation

The LC3plus encoder may change the length of a compressed audio frame (*nbytes*) in a seamless manner. To enable this, the encoder receives an external command to change the compressed frame size, which is applied to the current frame and subsequent frames. The decoder determines the bit rate from the received packet size.

Whenever the bit rate (*nbytes*) is changed, the variables describing the bit rate defined in clause 5.2.5 need to be updated. These variables control tuning parameter for the TNS (see clauses 5.3.8 and 5.4.6), the LTPF (see clauses 5.3.10 and 5.4.9) and the Time Domain Attack Detector (clause 5.3.6) modules.

## 5.8 High-resolution audio support

### 5.8.1 Overview

High-resolution audio typically stands for high sampling rates $f_s$, i.e. 48 kHz or 96 kHz, and high resolution and dynamic range for the audio sample, i.e. at least 24 bits per sample. The supported codec rates are therefore significantly higher compared to regular transmissions.

LC3plus features a high-resolution audio coding mode that operates at sampling rates 48 and 96 kHz and provides always an audio bandwidth of $\frac{f_s}{2}$, where Full-Band High Resolution (FBHR) stands for an audio bandwidth of 24 kHz and Ultra-Band High Resolution (UBHR) stands for an audio bandwidth of 48 kHz. The high-resolution mode supports all frame durations and a wide range of bitrates, see Table 5.2.

The main differences between the high-resolution mode and the normal coding mode are a different set of MDCT windows that exhibit a higher stop-band attenuation and the use of a 24-bit dynamic for the quantizer of the spectral coefficients. An exhaustive list of changes to the encoding and decoding procedure is stated below.

The high-resolution mode is not compatible to the other modes of LC3plus. The support and usage of the high-resolution mode shall be negotiated out of band.

## 5.8.2 Changes to the algorithm in high-resolution mode

The changes to the algorithm in order to operate in high-resolution mode are:

- Clause 5.2.2: the sampling rate index 5 is added for 96 kHz.
- Clause 5.3.4.3: the MDCT window is replaced by a high-resolution window. The coefficients of these windows are given in clause 5.9.2 with suffix _HR. Furthermore, the parameter $N_E$ is set to $N_F$ resulting in full encoding of the spectrum.
- Clause 5.3.4.4: band numbers and band limits are defined according to values in clause 5.9.1 with suffix _HR.
- Clause 5.3.4a.

For high resolution mode the near Nyquist detector is replaced by a tone detector which is based on a spectral flatness calculation. In this case the *near_nyquist_flag* is set to 1 if the inverse spectral flatness exceeds the tone detector threshold ($TD_{thresh}$) according to equation (217.0):

$$\frac{\frac{1}{N_b}\sum_{n=0}^{n<N_b} E_B(n)}{2^{\left(\frac{1}{N_b}\sum_{n=0}^{n<N_b} log_2\left(E_B(n)\right)\right)}} > TD_{thresh} \tag{217.0}$$

**Table 5.35a: $TD_{thresh}$ frame duration ($N_{ms}$)**

| $N_{ms}$ | $nn_{idx}$ |
|---|---|
| **2,5 ms** | 301 695 |
| **5 ms** | 382 564 |
| **7,5 ms** | 743 496 |
| **10 ms** | 83 402 |

- Clause 5.3.5: no bandwidth detection is carried out, i.e. the bandwidth *B* is set to $\frac{f_s}{2}$. Furthermore, $nbits_{bw}$ is set to zero and consequently no bandwidth information is encoded in the bitstream.
- Clause 5.3.6: no attack detection is carried out, i.e. the attack flag is defined to be 0.
- Clause 5.3.7.2.4: for $f_s = 96\,000\ Hz$ the parameter $g_{tilt} = 34$ is used.
- Clause 5.3.7.2.8: the compression factor 0,85 in formula (24) is replaced by the compression factor *cf*, which is calculated according to:

$$cf = \begin{cases} 0{,}6 \cdot 0{,}35 & for\ \boldsymbol{N_{ms}} = 10\ and\ nbits > 4\,400 \\ 0{,}6 \cdot 0{,}3 & for\ \boldsymbol{N_{ms}} = 7{,}5\ and\ nbits > 3\,300 \\ 0{,}6 \cdot 0{,}25 & for\ \boldsymbol{N_{ms}} = 5\ and\ nbits > 2\,300 \\ 0{,}6 \cdot 0{,}25 & for\ \boldsymbol{N_{ms}} = 2{,}5\ and\ nbits > 1\,150 \\ 0{,}6 \cdot 0{,}25 & for\ \boldsymbol{N_{ms}} = 1{,}25\ and\ nbits > 575 \\ 0{,}6 & else \end{cases} \tag{217.1}$$

- Clause 5.3.8: TNS parameters are taken from Table 5.36 where the entries with bandwidth FBHR are used when $f_s = 48\,000\ Hz$ and the entries with bandwidth UBHR are used when $f_s = 96\,000\ Hz$. No TNS is used with the frame duration of 1,25 ms.

**Table 5.36: TNS parameters for high-resolution mode**

| $N_{ms}$ | Bandwidth | num_tns_filters | start_freq(f) | stop_freq(f) | sub_start(f,s) | sub_stop(f,s) |
|---|---|---|---|---|---|---|
| 2,5 | FBHR | 1 | {3} | {100} | {{3, 51}} | {{51, 100}} |
| 2,5 | UBHR | 1 | {3} | {100} | {{3, 51}} | {{51, 100}} |
| 5 | FBHR | 2 | {6, 100} | {100, 200} | {{6, 53}, {100, 150}} | {{53, 100}, {150, 200}} |
| 5 | UBHR | 2 | {6, 100} | {100, 200} | {{6, 53}, {100, 150}} | {{53, 100}, {150, 200}} |
| 7,5 | FBHR | 2 | {9, 150} | {150, 300} | {{9, 56, 103}, {150, 200, 250}} | {{56, 103, 150}, {200, 250, 300}} |
| 7,5 | UBHR | 2 | {9, 150} | {150, 300} | {{9, 56, 103}, {150, 200, 250}} | {{56, 103, 150}, {200, 250, 300}} |
| 10 | FBHR | 2 | {12, 200} | {200, 400} | {{12, 74, 137}, {200, 266, 333}} | {{74, 137, 200}, {266, 333, 400}} |
| 10 | UBHR | 2 | {12, 200} | {200, 400} | {{12, 74, 137}, {200, 266, 333}} | {{74, 137, 200}, {266, 333, 400}} |

- Clause 5.3.10: LTPF analysis is carried out as is with $P = 2$ in equation $(76)$ and the threshold for pitch_present is changed from 0,6 to 0,4 in formula (88).

$$\text{pitch_present} = \begin{cases} 1 & \text{if } \text{normcorr}\left(x_{6,4}, corr_{len}, T_{curr}\right) > 0{,}4 \\ 0 & \text{otherwise} \end{cases} \quad (217.2)$$

- Clause 5.3.11.2: the value $nbits_{ari}$ is incremented by 1.
- Clause 5.3.11.3: if the sampling frequency is 96 kHz, i.e. $f_s^{ind} = 5$, the calculation of the global gain offset in equation (104) is changed to:

$$gg_{off} = \max\left(-\min\left(115, \left\lfloor \frac{nbits}{10 \cdot (f_s^{ind} + 1)} \right\rfloor\right) - 105 - 5 \cdot (f_s^{ind} + 1), \quad -181\right)$$

Then, a signal adaptive noise floor is added in the calculation of $E(k)$ in formula $(105)$, i.e. the value is calculated as:

$$E(k) = 10 \cdot \log_{10}\left(2^{-31} + \sum_{n=0}^{3} X_f(4 \cdot k + n)^2 + N\left(X_f\right)\right) \quad for\ k = 0 \ldots \frac{N_E}{4} - 1,$$

where $N\left(X_f\right)$ is defined by:

$$N\left(X_f\right) = \max_{k} \left|X_f(k)\right| \cdot 2^{-regBits - lowBits}.$$

The parameter $regBits$ depends on bitrate, frame duration and sampling frequency and is computed as:

$$regBits = \max\left(min\left(\left\lfloor \frac{br}{12\,500} \right\rfloor + C(N_{ms}, f_s),\ 23\right), 6\right)$$

with $C(N_{ms}, f_s)$ as specified in Table 5.37.

**Table 5.37: Parameter C for calculating regularization bits**

| $N_{ms} \setminus f_s$ | $f_s$ = 48 000 Hz | $f_s$ = 96 000 Hz |
|---|---|---|
| 1,25 | 0 | 0 |
| 2,5 | -6 | -6 |
| 5 | 0 | 0 |
| 7,5 | 2 | 1 |
| 10 | 2 | 5 |

The parameter $lowBits$ depends on the center of mass of the absolute values of the residual spectrum and is computed as:

$$lowBits = \frac{4}{N_{ms}}\left(2N_{ms} - \min\left(\frac{M_1}{M_0}, 2N_{ms}\right)\right),$$

where:

$$M_0 = \sum_{k=0}^{N_E-1} |X_f(k)| + 10^{-5}$$

and

$$M_1 = \sum_{k=0}^{N_E-1} k\ |X_f(k)| + 10^{-5}$$

are moments of the absolute spectrum.

Furthermore, the parameter $gg_{min}$ is calculated as:

$$gg_{min} = \begin{cases} \left\lfloor 28 \cdot \log 10\left(\frac{X_f^{max}}{8\,388\,606}\right) \right\rfloor - gg_{off} & \text{, if } X_f^{max} > 0 \\ 0 & \text{, otherwise.} \end{cases}$$

- Clause 5.3.11.4: the quantization offset is changed to 0,5, i.e. quantization is carried out according to:

$$X_q(n) = \begin{cases} \left\lfloor \frac{X_f(n)}{gg} + 0{,}5 \right\rfloor & \text{, if } X_f(n) \geq 0 \\ \left\lceil \frac{X_f(n)}{gg} - 0{,}5 \right\rceil & \text{, otherwise} \end{cases} \qquad for \;\; n = 0 \ldots N_E - 1.$$

- Clause 5.3.11.5: For 96 kHz *rateFlag* and *modeFlag* shall not be changed and initialized by *modeFlag* = -1 and *rateFlag* = 0.

- Clause 5.3.11.7: the lists t1, t2 and t3 are extended as follows: t1[5] = 830, t2[5] = 3 125, t3[5] = 5 100. Furthermore, the global gain adjustment is changed to:

```
if (gg_ind < 255 && nbits_est > nbits_spec)
{
    factor = 1;
     if (frame_ms == 1,25)
    {
        factor = 4;
    }

    else if (frame_ms == 2,5)
    {
        if(nbits_est < 520)
        {
            factor = 3;
        }
        else
        {
            factor = 4;
        }
    }
    else if (frame_ms == 5)
    {
        factor = 2;
    }
    else if (frame_ms == 7,5)
    {
        factor = 1,2;
    }

    gg_ind += floor(factor * ((nbits_est - nbits_spec)/delta + 1));
    gg_ind = min(gg_ind, 255);
}
```

- Clause 5.3.12: residual coding is extended to calculate at most 20 bits per non-zero quantized spectral coefficient. These residual bits are determined as to minimize the error term:

$$gg\left(X_q(k_i) - \sum_{j=1}^{n_i} (-1)^{b_i(j)} \cdot 2^{-j-1}\right) - X_f(k).$$

Calculation of the residual bits is carried out as follows. First the maximal number of residual coding bits is determined according to:

```
nbits_residual_max = nbits_spec - nbits_trunc + 14;
```

Then, the residual bits are computed according to the following pseudo code:

```
iter = 0;
nbits_residual = 0;
offset = 0.25;
while (nbits_residual < nbits_residual_max && iter < 20)
{
    k = 0;

    while (k < N_E && nbits_residual < nbits_residual_max)
    {
        if (X_q[k] != 0)
        {
            if (X_f[k] >= X_q[k]*gg)
            {
                res_bits[nbits_residual] = 1;
                X_f[k] -= offset * gg;
            }
            else
            {
                res_bits[nbits_residual] = 0;
                X_f[k] += offset * gg;
            }
            nbits_residual++;
        }
        k++;
    }
    iter++;
    offset /= 2;
}
```

- Clause 5.3.13: the parameter $bw_{stop}$ is set to $40N_{ms}$.

- Clause 5.4.2.7: the loop:

```
for (lev = 0; lev < 14; lev++)
```

is replaced by the loop

```
for (lev = 0; lev < 22; lev++).
```

- Clause 5.4.2.8: the loop:

```
/* Noise Filling Seed */
tmp = 0;
for (k = 0; k < N_E; k++)
{
 tmp += abs(X̂_q[k]) * k;
}
```

is replaced by:

```
/* Noise Filling Seed */
tmp = 0;
for (k = 0; k < N_E; k++)
{
 tmp += (abs(X̂_q[k])&32767) * k;
}
```

- Clause 5.4.3: residual decoding is performed according to the following pseudo code:

```
iter = n = 0;
offset = 0.25;
while (iter < 20 && n < nResBits)
{
    k = 0;
    while (k < N_E && n < nResBits)
    {
        if (X̂_q[k] != 0)
        {
            if (resBits[n++] == 0)
            {
                X̂_q[k] -= offset;
            }
            else
            {
```

```
                    X̂_q[k] +=offset;
                }
            }
            k++;
        }
        iter ++;
        offset /= 2;
    }
```

- Clause 5.4.9: no long-term post filtering is applied except for the frame duration of 1,25 ms.
- Clause 5.6.3.1: as frequency domain concealment (Phase ECU) is not available for 96 kHz sampling rate, time domain concealment is selected instead if $T_c > 0$ and $class \leq 0$ and $N_{ms} = 10$.

  For 48 kHz sampling rate and 10 ms frame duration, either this modified method selection or the original method in clause 5.6.3.1 shall be used.

### 5.8.3 Void

## 5.9 Tables and constants

### 5.9.1 Band tables index

The values representing the variable $I_{fs}(n)$ can be found under ./src/floating_point/constants.c contained in archive ts_103634v010701p0.zip which accompanies the present document.

$I_{fs}(n)$ for 1,25 ms frame duration:

```
ACC_COEFF_PER_BAND_16_1_25ms[21]
ACC_COEFF_PER_BAND_24_1_25ms[28]
ACC_COEFF_PER_BAND_32_1_25ms[32]
ACC_COEFF_PER_BAND_48_1_25ms[34]
ACC_COEFF_PER_BAND_48_1_25ms_HR[36]
ACC_COEFF_PER_BAND_96_1_25ms_HR[42]
ACC_COEFF_PER_BAND_192_1_25ms_HR[46]
```

$I_{fs}(n)$ for 2,5 ms frame duration:

```
ACC_COEFF_PER_BAND_8_2_5ms[21]
ACC_COEFF_PER_BAND_16_2_5ms[36]
ACC_COEFF_PER_BAND_24_2_5ms[41]
ACC_COEFF_PER_BAND_32_2_5ms[44]
ACC_COEFF_PER_BAND_48_2_5ms[45]
ACC_COEFF_PER_BAND_48_2_5ms_HR[46]
ACC_COEFF_PER_BAND_96_2_5ms_HR[50]
ACC_COEFF_PER_BAND_192_2_5ms_HR[53]
```

$I_{fs}(n)$ for 5 ms frame duration:

```
ACC_COEFF_PER_BAND_8_5ms[40]
ACC_COEFF_PER_BAND_16_5ms[51]
ACC_COEFF_PER_BAND_24_5ms[53]
ACC_COEFF_PER_BAND_32_5ms[55]
ACC_COEFF_PER_BAND_48_5ms[56]
ACC_COEFF_PER_BAND_48_5ms_HR[56]
ACC_COEFF_PER_BAND_96_5ms_HR[59]
ACC_COEFF_PER_BAND_192_5ms_HR[60]
```

$I_{fs}(n)$ for 7,5 ms frame duration:

```
ACC_COEFF_PER_BAND_8_7,5ms[61]
ACC_COEFF_PER_BAND_16_7,5ms[65]
ACC_COEFF_PER_BAND_24_7,5ms[65]
ACC_COEFF_PER_BAND_32_7,5ms[65]
ACC_COEFF_PER_BAND_48_7,5ms[65]
ACC_COEFF_PER_BAND_48_7,5ms_HR[65]
ACC_COEFF_PER_BAND_96_7,5ms_HR[65]
ACC_COEFF_PER_BAND_192_7,5ms_HR[65]
```

$I_{fs}(n)$ for 10 ms frame duration:

```
ACC_COEFF_PER_BAND_8[65]
ACC_COEFF_PER_BAND_16[65]
ACC_COEFF_PER_BAND_24[65]
ACC_COEFF_PER_BAND_32[65]
ACC_COEFF_PER_BAND_48[65]
ACC_COEFF_PER_BAND_48_HR[65]
ACC_COEFF_PER_BAND_96_HR[65]
ACC_COEFF_PER_BAND_192_HR[65]
```

## 5.9.2 Low delay MDCT windows

### 5.9.2.0 Frame size 1,25 ms

**Table 5.37a: MDCT windows for 1,25 ms**

| $w_{N_{ms_}N_F}$ | Constant name in ./src/floating_point/constants.c |
|---|---|
| $w_{1,25_20}$ | MDCT_WINDOW_160_1_25ms[40] |
| $w_{1,25_30}$ | MDCT_WINDOW_240_1_25ms[60] |
| $w_{1,25_40}$ | MDCT_WINDOW_320_1_25ms[80] |
| $w_{1,25_60}$ | MDCT_WINDOW_480_1_25ms[120] |
| $w_{1,25_60_HR}$ | MDCT_HRA_WINDOW_480_1_25ms[120] |
| $w_{1,25_120_HR}$ | MDCT_HRA_WINDOW_960_1_25ms[240] |
| $w_{1,25_240_HR}$ | MDCT_HRA_WINDOW_1920_1_25ms[480] |

### 5.9.2.1 Frame size 2,5 ms

Note that the non HR windows are a symmetric Kaiser-Bessel-Derived windows as defined in [i.14] with $\alpha\pi = 10$. The values representing the variable $w_{N_{ms_}N_F}$ can be found under ./src/floating_point/constants.c contained in archive ts_103634v010701p0.zip which accompanies the present document.

**Table 5.38: MDCT windows for 2,5 ms**

| $w_{N_{ms_}N_F}$ | Constant name in ./src/floating_point/constants.c |
|---|---|
| $w_{2,5_20}$ | MDCT_WINDOW_80_2_5ms[40] |
| $w_{2,5_40}$ | MDCT_WINDOW_160_2_5ms[80] |
| $w_{2,5_60}$ | MDCT_WINDOW_240_2_5ms[120] |
| $w_{2,5_80}$ | MDCT_WINDOW_320_2_5ms[160] |
| $w_{2,5_120}$ | MDCT_WINDOW_480_2_5ms[240] |
| $w_{2,5_120_HR}$ | MDCT_HRA_WINDOW_480_2_5ms[240] |
| $w_{2,5_240_HR}$ | MDCT_HRA_WINDOW_960_2_5ms[480] |
| $w_{2,5_480_HR}$ | MDCT_HRA_WINDOW_1920_2_5ms[960] |

### 5.9.2.2 Frame size 5 ms

**Table 5.39: MDCT windows for 5 ms**

| $w_{N_{ms_}N_F}$ | Constant name in ./src/floating_point/constants.c |
|---|---|
| $w_{5_40}$ | MDCT_WINDOW_80_5ms[80] |
| $w_{5_80}$ | MDCT_WINDOW_160_5ms[160] |
| $w_{5_120}$ | MDCT_WINDOW_240_5ms[240] |
| $w_{5_160}$ | MDCT_WINDOW_320_5ms[320] |
| $w_{5_240}$ | MDCT_WINDOW_480_5ms[480] |
| $w_{5_240_HR}$ | MDCT_HRA_WINDOW_480_5ms[480] |
| $w_{5_480_HR}$ | MDCT_HRA_WINDOW_960_5ms[960] |
| $w_{5_960_HR}$ | MDCT_HRA_WINDOW_1920_5ms[1920] |

#### 5.9.2.3 Frame size 7,5 ms

**Table 5.39a: MDCT windows for 7,5 ms**

| $w_{N_{ms}_N_F}$ | Constant name in ./src/floating_point/constants.c |
|---|---|
| $w_{7,5_60}$ | MDCT_WINDOW_80_7_5ms[120] |
| $w_{7,5_120}$ | MDCT_WINDOW_160_7_5ms[240] |
| $w_{7,5_180}$ | MDCT_WINDOW_240_7_5ms[360] |
| $w_{7,5_240}$ | MDCT_WINDOW_320_7_5ms[480] |
| $w_{7,5_360}$ | MDCT_WINDOW_480_7_5ms[720] |
| $w_{7,5_360_HR}$ | MDCT_HRA_WINDOW_480_7_5ms[720] |
| $w_{7,5_720_HR}$ | MDCT_HRA_WINDOW_960_7_5ms[1440] |
| $w_{7,5_1440_HR}$ | MDCT_HRA_WINDOW_1440_7_5ms[2880] |

#### 5.9.2.4 Frame size 10 ms

**Table 5.40: MDCT windows for 10 ms**

| $w_{N_{ms}_N_F}$ | Constant name in ./src/floating_point/constants.c |
|---|---|
| $w_{10_80}$ | MDCT_WINDOW_80[160] |
| $w_{10_160}$ | MDCT_WINDOW_160[320] |
| $w_{10_240}$ | MDCT_WINDOW_240[480] |
| $w_{10_320}$ | MDCT_WINDOW_320[640] |
| $w_{10_480}$ | MDCT_WINDOW_480[960] |
| $w_{10_480_HR}$ | MDCT_HRA_WINDOW_480_10ms[960] |
| $w_{10_960_HR}$ | MDCT_HRA_WINDOW_960_10ms[1920] |
| $w_{10_1920_HR}$ | MDCT_HRA_WINDOW_1920_10ms[3840] |

### 5.9.3 SNS quantization

**Table 5.41: Tables for SNS quantization**

| Variable in the present document | Constant name in ./src/floating_point/constants.c. |
|---|---|
| LFCB | sns_C1[8][32] |
| HFCB | sns_C2[8][32] |
| sns_vq_reg_adj_gains | sns_vq_reg_adj_gains_fl[2] |
| sns_vq_reg_lf_adj_gains | sns_vq_reg_lf_adj_gains_fl[4] |
| sns_vq_near_adj_gains | sns_vq_near_adj_gains_fl[4] |
| sns_vq_far_adj_gains | sns_vq_far_adj_gains_fl[8] |
| MPVQ_offsets | pvq_enc_A[16][11] |
| **Variable in the present document** | **Constant name in ./src/ fixed_point/constants.c.** |
| sns_gainMSBbits | sns_gainMSBbits[4] |
| sns_gainLSBbits | sns_gainLSBbits[4] |

NOTE: The matrix D[16][16] described below is used for the calculation in equation (40). The fix-point reference source code uses an in-place DCT-II function to do this calculation with pre-calculated constants.

```
double D[16][16] = {
/* D consists of the base vectors of the DCT (orthogonalized DCT-II)*/
/* (the DCT base vector are stored in column-wise in this table)*/
/* first row results in the first coeff in fwd synthesis (dec+(enc))*/
/* first column results in the first coeff in the analysis(encoder) */

## 5.10 Lossless audio support

### 5.10.1 Introduction

In the lossless operation mode, LC3plus allows bit-exact reconstruction of the encoded audio input signal on the decoder side. The supported codec rates are therefore higher compared to regular or high-resolution mode. In case of bitrate restrictions (CBR mode), the LC3plus lossless mode features an automatic and seamless (on a frame-by-frame basis) switching to high-resolution mode if the given bit budget is not sufficient for lossless encoding of the input audio data. Whenever the bit budget is sufficient for lossless encoding, the codec switches back to lossless mode. Given this, LC3plus provides at any time the coding mode with the highest quality possible for any given bit rate requirement, either lossless or high-resolution mode, dynamically switching between the modes at runtime. If no bitrate restriction applies, LC3plus in lossless mode continually provides lossless coding and determines the required bitrate for lossless coding itself.

Independently of the bitrate restriction setting, LC3plus lossless mode bounds the maximum encoded payload size per frame and channel through an integrated time-domain WTDA verbatim fallback path (clause 5.10.2.1.16). Whenever the transform-domain lossless and high-resolution coding paths would together exceed the payload limit of fallback_num_bytes bytes (defined in equation 217.17), the encoder emits the audio frame in WTDA verbatim form, which carries one sign bit plus bits_per_audio_sample magnitude bits per audio sample. This fallback path guarantees a deterministic maximum bitrate of (bits_per_audio_sample + 1) $f_s$ per channel, independently of the input signal characteristics.

Under a bitrate restriction (constrained bit rate operation), the encoder may optionally emit every frame at the fixed frame size *nbytes* by appending a padding pattern to frames whose net payload would otherwise fall below the value of *nbytes*. The padding pattern is defined in clause 5.10.2.1.17 and is removed by the decoder as described in clause 5.10.2.2.1.

LC3plus lossless audio coding mode operates at sampling rates of 44,1 kHz, 48 kHz, 96 kHz and 192 kHz and provides always an audio bandwidth of $\frac{f_s}{2}$. The lossless mode supports all frame durations and a wide range of bitrates, see Table 5.2a.

The main differences between the lossless and the high-resolution mode are a new implementation of the MDCT with losslessly invertible arithmetic and methods for estimation of the required amount of bits for lossless encoding, allowing for the dynamic switching to high-resolution coding if the given budget is exceeded. Clause 5.10.2 elaborates on the differences to HR mode.

The lossless mode is not compatible to the other modes of LC3plus, not even with the high-resolution mode described in clause 5.8. The support and usage of the lossless mode as well as the amount of bits per PCM sample shall be negotiated out of band.

Figure 5.13 (encoder part) and figure 5.14 (decoder part) show block diagrams explaining the major structural differences between high-resolution mode and lossless mode of the LC3plus.

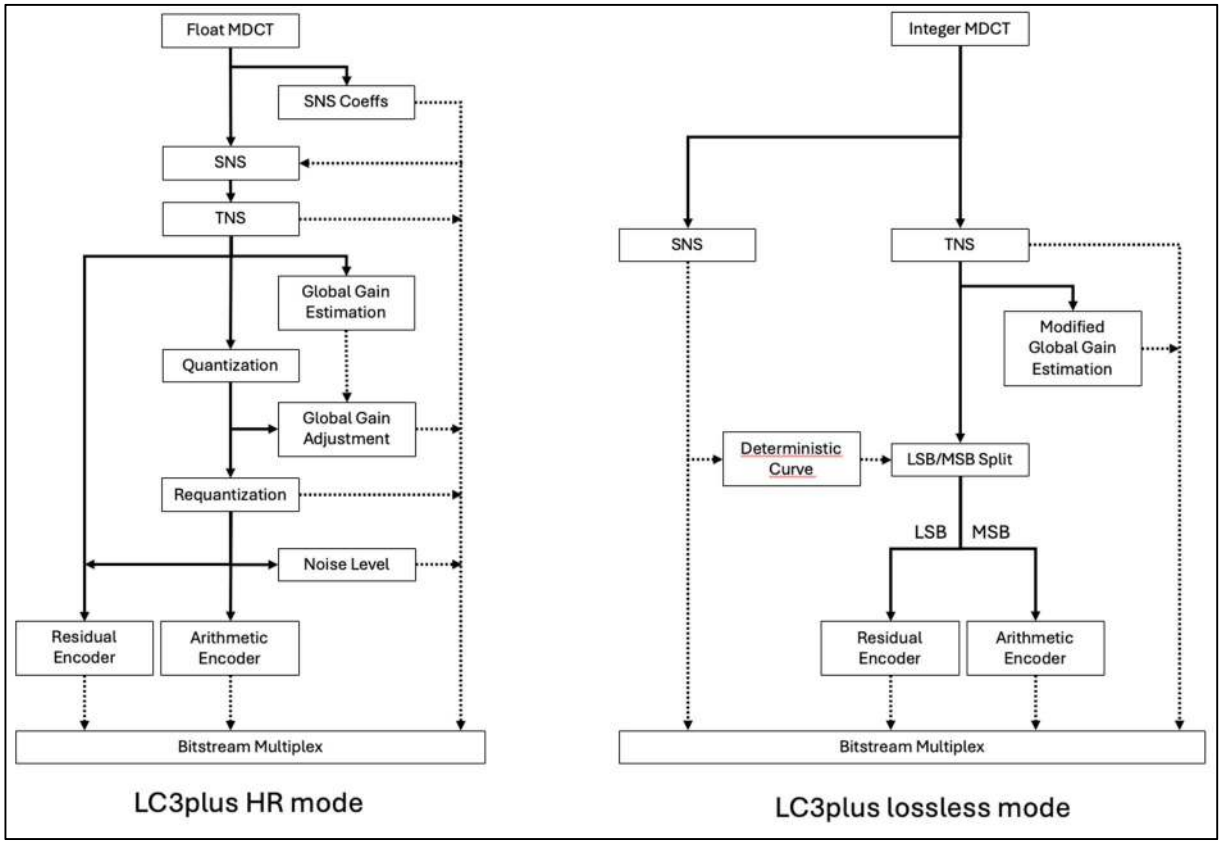

**Figure 5.13: Structural difference High-Resolution vs. Lossless mode (encoder part)**

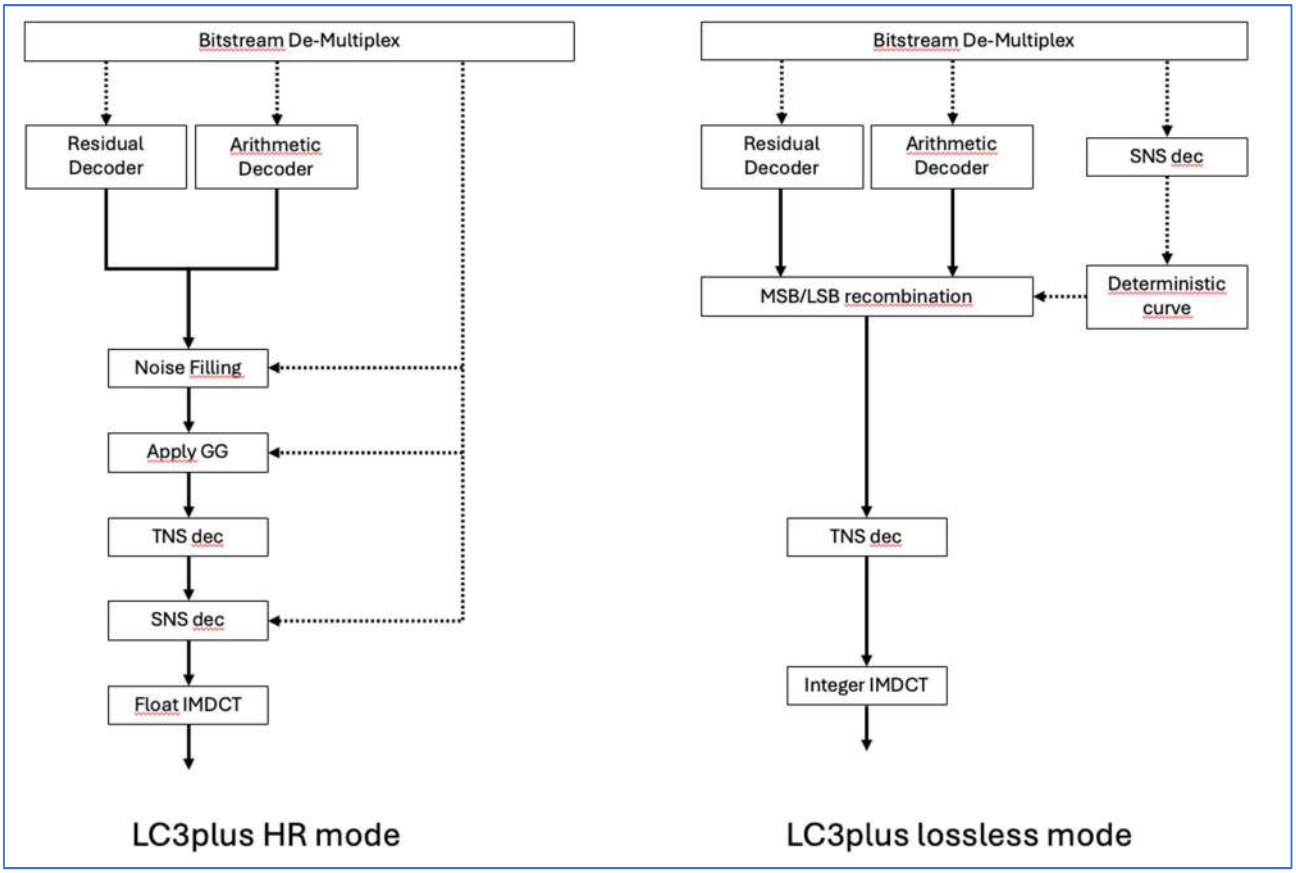

**Figure 5.14: Structural difference High-Resolution vs. Lossless mode (decoder part)**

If the bit estimation process (see clauses 5.10.2.1.6 and 5.10.2.1.15) reveals that the frame under consideration can not be encoded as lossless within the given bitrate constraints (if any), the frame is encoded in HR mode. The decision is made for each frame such that dynamic switching between lossless and HR coding is done on a frame-by-frame base. The secondary decision logic and subsequent resulting processing steps are shown in Figure 5.15 for encoding and Figure 5.16 for decoding. The primary decision logic is described in clause 5.10.2.1.6.

As outlined in the Figures below, the LC3plus lossless contains three coding paths:

- a transform-domain-based encoding and decoding processing, using a losslessly invertible arithmetic;
- a transform-domain-based encoding and decoding processing, using a perceptual motivated scale factor-based scaling; and
- a time-domain-based encoding and decoding processing (fallback mode), which is used to limit the maximum payload size.

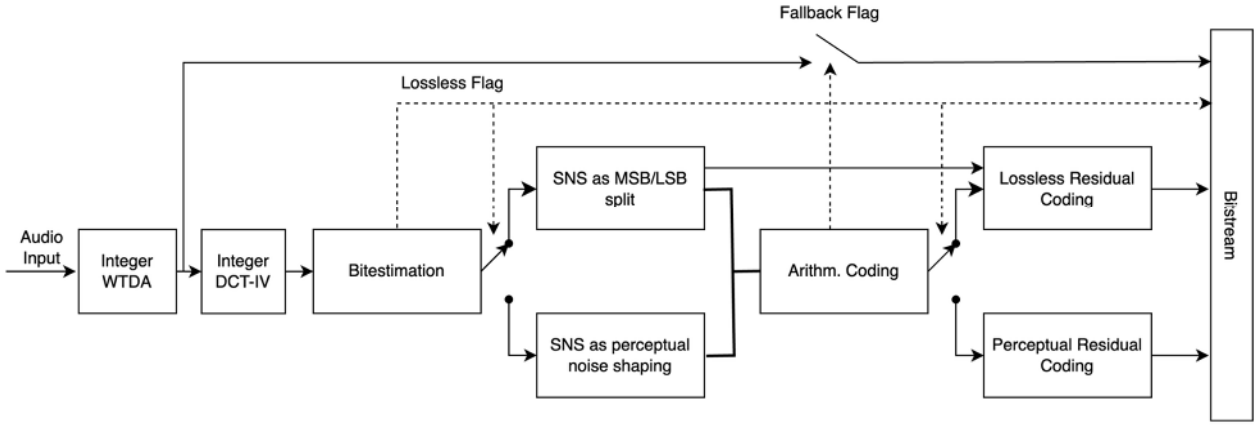

**Figure 5.15: Dynamic switching High-Resolution ⇔ Lossless mode (encoder part)**

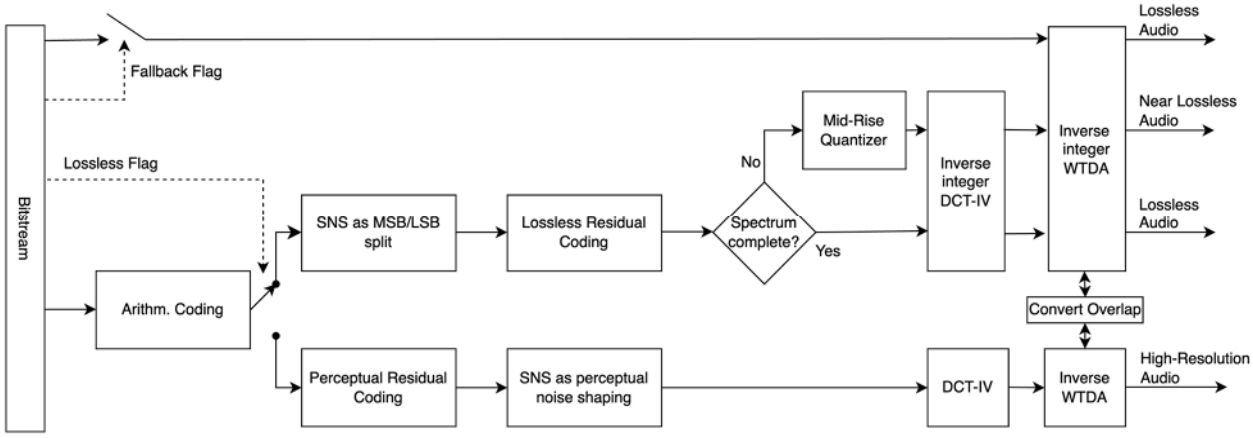

**Figure 5.16: Dynamic switching High-Resolution ⇔ Lossless mode (decoder part)**

## 5.10.2 Changes to the algorithm in lossless mode

### 5.10.2.1 Encoding process

#### 5.10.2.1.1 Input signal (clause 5.3.2)

Only 16 or 24 bits per sample are supported for lossless. 32 bits per sample are not supported.

#### 5.10.2.1.2 Input signal scaling (clause 5.3.3)

In lossless mode the input signal does not undergo any scaling operation and therefore the values format is denoted as Q31.

The lossless mode includes a signal-shifting option for 24-bit-per-sample input. The input samples of each frame are right-shifted by a value between 0 and 8 bits before the MDCT analysis. The shift value is written into the bitstream, and on the decoder side the signal is left-shifted by the same value after the inverse MDCT synthesis. The shift is applied per frame and may change between consecutive frames. Signal shifting is supported for all frame sizes and sample rates. To use it in constraint-bitrate mode, a minimum bitrate is required as specified in tables 5.43a-c.

**Table 5.43a: Minimum Bitrate $f_s \in [44\,100, 48\,000]$**

| Frame Duration (ms) | Minimum Bitrate (bits/s) |
|---|---|
| 10 / 7,5 | 124 800 |
| 5 | 148 800 |
| 2,5 | 172 800 |
| 1,25 | 204 800 |

**Table 5.43b: Minimum Bitrate $f_s \in [96\,000]$**

| Frame Duration (ms) | Minimum Bitrate (bits/s) |
|---|---|
| 10 / 7,5 | 149 600 |
| 5 | 174 400 |
| 2,5 | 194 800 |
| 1,25 | 230 400 |

**Table 5.43c: Minimum Bitrate $f_s \in [192\,000]$**

| Frame Duration (ms) | Minimum Bitrate (bits/s) |
|---|---|
| 10 / 7,5 | 199 200 |
| 5 | 225 600 |
| 2,5 | 249 600 |
| 1,25 | 249 600 |

If the shift value changes between frames, the overlap-add memory needs to be shifted by the difference between the previous frame's and the current frame's shift value. If the current frame's shift value is higher than the previous one, the memory is right-shifted by delta = current_shift_value − previous_shift_value. If the previous frame has the higher value, it is left-shifted by delta = previous_shift_value − current_shift_value.

#### 5.10.2.1.3 Low Delay MDCT analysis (clause 5.3.4)

##### 5.10.2.1.3.1 Overview

The low delay MDCT shall be implemented using a lifting scheme which allows to stay in the integer domain. For the integer version of the low delay MDCT, the MDCT operation is divided into a Windowing - Time Domain Aliasing stage (WTDA) and a DCT-IV stage.

Each stage shall be implemented bit-exact in comparison to the C reference code. Therefore, the exact window coefficients, rounding and scaling operations of the fixed-point code need to be preserved.

##### 5.10.2.1.3.2 WTDA analysis stage

The WDTA combines the windowing operation and the time domain aliasing operation. The WTDA stage is illustrated by Figure 5.17, where x(k) with k=0...N/2-1 are the integer audio samples of the current block. A negative index indicates samples from previous block.

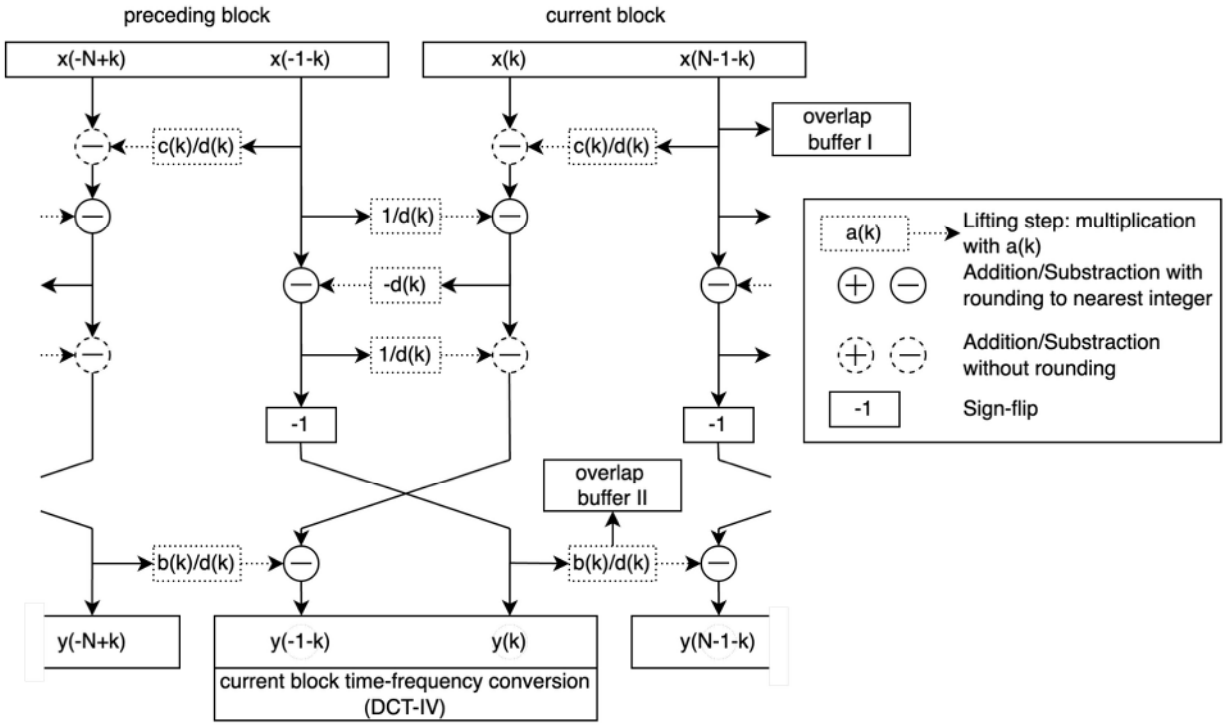

**Figure 5.17: Detailed description of WTDA analysis stage**

The vector [y(-1-k) y(k)] is the time domain input to the DCT-IV stage, which conducts the time-frequency conversion. a(k),b(k),c(k),d(k) are portions of window coefficients defined by:

- a(k) = w($N_F$-1-k), b(k) = -w(k), c(k) = w(2$N_F$-1-k), d(k) = w($N_F$+k), with w(j) for j = 0, …, 2$N_F$-1 denoting the analysis high-resolution window coefficients, see clause 5.8.2.

The windows have typically an asymmetric shape with a leading zero section of Z samples. As Z is part of c(k), the first lifting step can partly be omitted. In each lifting step, the floating-point coefficients are multiplied with the corresponding input value, followed by a linear combination and depending on whether a second lifting step is applied to the signal path, a rounding operation to the nearest integer in format Q31 is applied. Therefore, at any stage the signal is represented as integer numbers.

The overlap-add buffer consists of two segments where the overlap buffer II stores an intermediate (non-rounded / floating-point) signal in Q33.

The bit-exact reference implementation is provided in the file src/fixed-point/intDCT_fx.c.

5.10.2.1.3.3 Integer DCT-IV stage

The DCT-IV of length $N$ is decomposed in the following way

$$DCTIV_N = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \begin{pmatrix} 1 & & & & & & cs(0) \\ & \ddots & & & & \iddots & \\ & & 1 & cs(N/2-1) & & & \\ & & & 1 & & & \\ & & & & \ddots & & \\ & & & & & & 1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & & & & & \\ & \ddots & & & & \\ & & 1 & & & \\ & & s(N/2-1) & 1 & & \\ & \iddots & & & \ddots & \\ s(0) & & & & & 1 \end{pmatrix} \begin{pmatrix} 1 & & & & & & cs(0) \\ & \ddots & & & & \iddots & \\ & & 1 & cs(N/2-1) & & & \\ & & & 1 & & & \\ & & & & \ddots & & \\ & & & & & & 1 \end{pmatrix}$$

$$\begin{pmatrix} I & \frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix} \begin{pmatrix} I & 0 \\ -\sqrt{2}DCTIV_{N/2} & I \end{pmatrix} \begin{pmatrix} I & \frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix} \begin{pmatrix} I & -\frac{1}{2}I \\ 0 & I \end{pmatrix} \begin{pmatrix} I & 0 \\ I & I \end{pmatrix} QP$$

$$DCTIV_N = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \begin{pmatrix} 1 & & & & & & cs(0) \\ & \ddots & & & & \iddots & \\ & & 1 & cs(N/2-1) & & & \\ & & & 1 & & & \\ & & & & \ddots & & \\ & & & & & & 1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & & & & & \\ & \ddots & & & & \\ & & 1 & & & \\ & & s(N/2-1) & 1 & & \\ & \iddots & & & \ddots & \\ s(0) & & & & & 1 \end{pmatrix} \begin{pmatrix} 1 & & & & & & cs(0) \\ & \ddots & & & & \iddots & \\ & & 1 & cs(N/2-1) & & & \\ & & & 1 & & & \\ & & & & \ddots & & \\ & & & & & & 1 \end{pmatrix}$$

$$\begin{pmatrix} I & \frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix} \begin{pmatrix} I & 0 \\ -\sqrt{2}DCTIV_{N/2} & I \end{pmatrix} \begin{pmatrix} I & \frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix} \begin{pmatrix} I & -\frac{1}{2}I \\ 0 & I \end{pmatrix} \begin{pmatrix} I & 0 \\ I & I \end{pmatrix} QP$$

with the values

$$s(k) = \sin\frac{(2k+1)\pi}{4N}, \quad cs(k) = \frac{\cos\frac{(2k+1)\pi}{4N} - 1}{\sin\frac{(2k+1)\pi}{4N}}, \quad k = 0,...,N/2-1$$

and the permutation matrices $P$ and $Q$ with:

$$P_{4k,4k} = P_{4k+1,4k+1} = P_{4k+2,4k+3} = P_{4k+3,4k+2} = 1, \quad k = 0,...,N/4-1$$
$$P_{k,l} = 0 \quad else$$

i.e. every second pair of values is swapped, and

$$Q_{k,2k} = Q_{N/2+k,2k+1} = 1, \quad k = 0,...,N/2-1$$
$$Q_{k,l} = 0 \quad else$$

i.e. the even indices are arranged in the first half, the odd indices are arranged in the second half.

The bit-exact reference implementation is provided in intDCT_fx.c including the FFT implementations in file fft.c.

5.10.2.1.3.4 Energy estimation per band (clause 5.3.4.4)

For $f_s = 192\,000$ Hz and 24 bits per sample PCM input the limit of the evaluation interval changes from $N_b - 1$ to $N_b - 13$, where $N_b$ is the band number.

#### 5.10.2.1.4 Spectral Noise Shaping (clause 5.3.7)

Smoothing (clause 5.3.7.2.3), pre-emphasis (clause 5.3.7.2.4) and noise floor (clause 5.3.7.2.5) are deactivated for all lossless frames. Noise floor is set to 1 (i.e. the minimum value) in this case.

For scaling of SNS coefficients (clause 5.3.7.2.8), the compression factor $0{,}85$ in equation $(24)$ is replaced by 1,0 for lossless frames (ll_adap_flag = 1).

Scale factor smoothing (eq. 25.1 to 25.4 and 26 to 31) is skipped for all frames.

For $f_s = 192\,000$ Hz and 24 bits per sample PCM input the SNS analysis is executed on a reduced number of bands with $N_{b_r} = \mathrm{N_b} - 12$.

For $N_{ms} = 1{,}25$ ms, the Low Rate SNS quantization defined in clause 5.3.7.3a shall be used instead of the regular SNS quantization. The deactivation of smoothing, pre-emphasis and noise floor described above apply only to the regular SNS workflow and not to the Low Rate SNS workflow.

#### 5.10.2.1.5 Bandwidth Control (clause 5.3.8)

Bandwidth control is skipped for all frames.

#### 5.10.2.1.6 Temporal Noise Shaping (clause 5.3.9)

For lossless frames, TNS works as a prediction tool optimizing the compression gain while for high-resolution frames, TNS works as a perceptual tool improving the audio quality. To maximize the compression gain for lossless frames and maintaining the maximum number of valid bits, TNS filtering is applied on a spectral representation with adaptively controlled precision. The goal is to adapt the number of coded bitplanes to allow lossless coding of the TNS filtered signal. This avoids any noise shaping effect which would result in low SNR values for these frame.

In lossless mode TNS filtering is enabled without a precision reduced representation if no bitrate restrictions apply and/or $N_{ms}$ = 2,5 ms, whereas in lossless CBR mode and $N_{ms} \neq 2{,}5$ ms the spectral precision where each TNS filter is applied is controlled adaptively as shown in figure 5.18. The near-Nyquist condition for the calculation of the TNS filters (clause 5.3.4a) still applies on top.

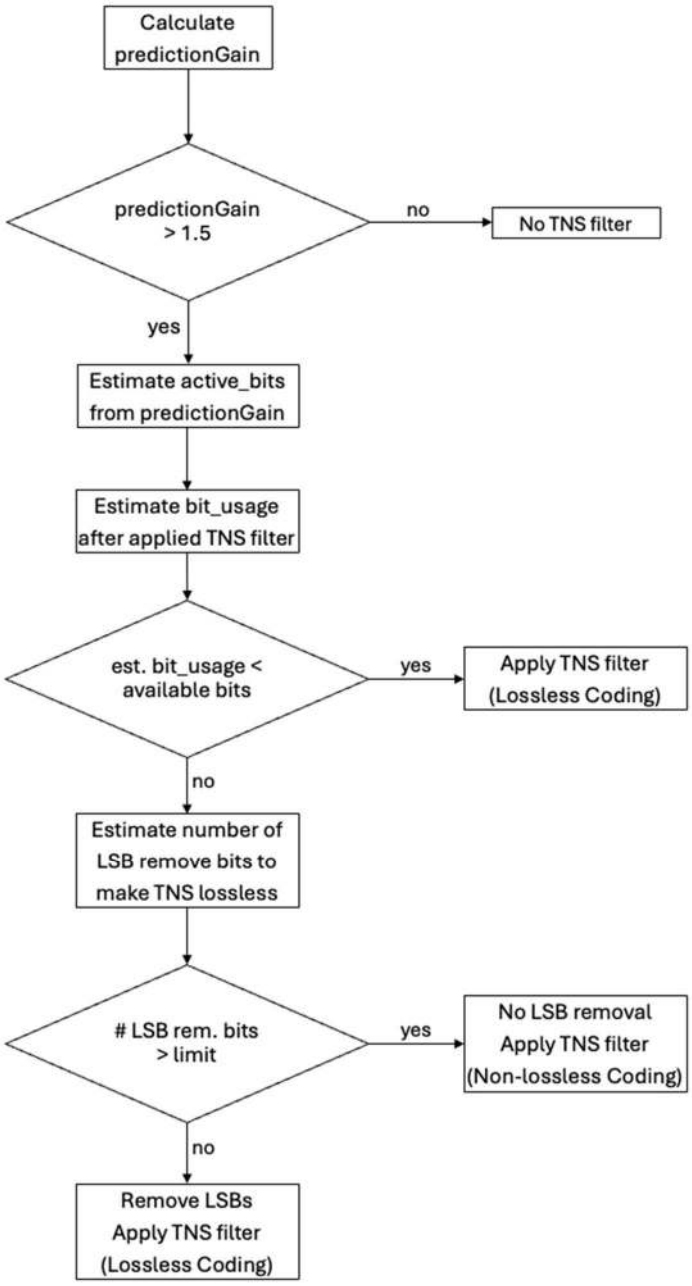

**Figure 5.18: Adaptive invocation of TNS**

In Figure 5.18 the following logical blocks can be identified:

- Calculation of *predictionGain* (see equation 67)
- Estimation of *active_bits_before*:

$$active_bits_before(f) = \sum_{s=0}^{2} \sum_{n=\text{sub_start}(f,s)}^{\text{sub_stop(f,s)-1}} \lceil log2(|X_s(\text{n})|) \rceil \quad \text{for f} = 0 \ldots \text{num_tns_filters} - 1 \tag{217.3}$$

- Estimation of *active bits* after application of TNS filter:

$$active_bits = \sum_{f=0}^{\text{num_tns_filters-1}} active_bits_before(\text{f}) \cdot active_bits_ratio(\text{f}) \tag{217.4}$$

where:

$$active_bits_ratio(0) = -0{,}0242 \cdot 10 \cdot log_{10}\big(predGain(0)\big) + 0{,}9681$$
$$active_bits_ratio(1) = -0{,}0356 \cdot 10 \cdot log_{10}\big(predGain(1)\big) + 1{,}0014 \quad (217.5)$$

- Bit usage estimation (*bit_usage_estimate*) from *active_bits* (see clause 5.10.2.1.15.2)
- Estimation of number of LSB bits that can be removed to still have TNS lossless (*tns_lsb_remove*):

$$tns_lsb_remove = \left\lceil \frac{bit_usage_estimate - nbits}{N_F} \right\rceil \quad (217.6)$$

with *nbits* as defined in clause 5.2.5 and

$$limit = \begin{cases} 4 & for\ 16\ bits\ per\ sample\ PCM\ input, \\ 8 & else. \end{cases} \quad (217.6a)$$

As can be derived from figure 5.18, the decision if the current frame can be encoded in lossless mode (ll_adap_flag = 1) or in high-resolution mode (ll_adap_flag = 0) is made as follows (note that this applies in CBR mode only as lossless encoding is possible for any frame if no bitrate restrictions apply):

- ll_adap_flag = 0 if any of the following conditions is met, else ll_adap_flag = 1:
  - $predGain(0) \leq 1{,}5$
  - $predGain(1) \leq 1{,}5$
  - $tns_lsb_remove > limit$

In case the energy of the TNS filtered signal is greater than the energy of the unfiltered signal, the filtering process is reverted and the unfiltered signal is used for further processing and ll_adap_flag is set to 0.

In case of applying the TNS filter without LSB removal (non-lossless coding) or $N_{ms}$ = 2,5 ms, i.e. ll_adap_flag = 0 after the TNS stage, a second bit usage estimation is performed to check if the spectrum might still be coded lossless (see clause 5.10.2.1.15.2).

The corresponding reference implementation is provided in source file tns_coder_fx.c where the filtering operation FIRlattice() needs to bit-exact.

### 5.10.2.1.7 Long Term Post Filter (clause 5.3.10)

LTPF is deactivated by setting ltpf_active to 0 (see clause 5.3.10) for lossless frames (ll_adap_flag = 1). For the frame duration of 1,25 ms, LTPF shall also remain deactivated, i.e. also in HR-fallback frames (ll_adap_flag = 0) within a lossless configuration, overriding the HR-mode behavior described in clause 5.8.2.

### 5.10.2.1.8 Spectral Quantization (clause 5.3.11)

For lossless frames the global gain estimation is changed as follows: Instead of inputting the number of target bits as the overall number of frame bits minus side info ($nbits$ in eq. 104), a tuned number of bits (*ll_ari_bits*) is given to the global gain estimation:

$$ll_ari_bits = \min(ll_ari_bits_raw, nbits) \quad (217.6b)$$

with *ll_ari_bits_raw* as defined in tables 5.44 to 5.46 (where *active_bits* is defined as $N_{ab}$ in clause 5.10.2.1.15.2).

The global gain offset is then calculated as described in tables 5.47 and 5.48 for all frame durations except for 1,25 ms. For 1,25 ms frame duration, the global gain offset is calculated according to clause 5.3.11.3 using the tilt vector, independently of $f_s$ and bits per sample.

**Table 5.44: ll_ari_bits_raw_for $f_s \in [44\,100, 48\,000]$**

| Bits per sample | ll_ari_bits |
|---|---|
| 16 | $\max\left(0, \min\left(-0{,}1125 \cdot \text{active_bits} + 2\,100, nbits\right)\right) \cdot \frac{N_F}{480}$ |
| 24 | $1\,750 \cdot \frac{N_{ms}}{10}$ |

**Table 5.45: ll_ari_bits_raw_for $f_s = 96\,000$**

| Bits per sample | ll_ari_bits |
|---|---|
| 16 | $4\,100 \cdot \frac{N_{ms}}{10}$ |
| 24 | $\max\left(0, \min\left(-0{,}4 \cdot \text{active_bits} + 7\,800, 6\,000\right)\right) \cdot \frac{N_F}{960}$ |

**Table 5.46: ll_ari_bits_raw and ll_ari_bits_raw_lb for $f_s = 192\,000$**

| Bits per sample | ll_ari_bits |
|---|---|
| 16 | $\max\left(0, \min\left(6\,000, -0{,}1906 \cdot \text{active_bits} + 7\,978\right)\right) \cdot \frac{N_F}{1\,920}$ |
| 24 | $\text{ll_ari_bits_raw} = \max\left(0, \min\left(6\,000, -0{,}175 \cdot \text{active_bits} + 7\,038\right)\right) \cdot \frac{N_F}{1\,920}$<br>$\text{ll_ari_bits_raw_lb} = \max\left(0, \min\left(-0{,}4 \cdot \text{active_bits_lb} + 7\,800, 6\,000\right)\right) \cdot \frac{N_F}{960}$ |

For $f_s = 192\,000$ Hz and 24 bits per sample PCM input an additional number of tuned bits (ll_ari_bits_raw_lb) is determined and used as direct input to the global gain estimation.

The *active_bits_lb* are calculated in the same way like the default active bits but on a limited range:

$$active_bits_lb = \sum_{k=0}^{I_{fs}(N_b-12)-1} (\lfloor \log2(\max(1, |X_F(k)|)) \rfloor + 1) \qquad (217.6c)$$

The global gain offset is then calculated as described in tables 5.47 to 5.48.

**Table 5.47: quantized gain offset for $f_s \in [44\,100, 48\,000]$**

| Bits per sample | quantizedGainOff_ll |
|---|---|
| 16 | $-\left(\min\left(115, \frac{ll_ari_bits}{10 \cdot \left(f_S^{ind} + 1\right)}\right) + 105 + 5 \cdot \left(f_S^{ind} + 1\right)\right)$ |
| 24 | $48 - \left(\min\left(115, \frac{ll_ari_bits}{10 \cdot \left(f_S^{ind} + 1\right)}\right) + 105 + 5 \cdot \left(f_S^{ind} + 1\right)\right)$ |

**Table 5.48: quantized gain offset for $f_s \in [96\,000, 192\,000]$**

| Bits per sample | quantizedGainOff_ll |
|---|---|
| 16 | $-\left(\min\left(115, \frac{ll_ari_bits}{10 \cdot (f_S^{ind} + 1)}\right) + 105 + 5 \cdot (f_S^{ind} + 1)\right)$ |
| 24 | $\text{nint}\left(\frac{-off_idx \cdot 100}{7} - 135\right) + 48$<br>where<br>$off_idx = -nint\left(\frac{(135 + \text{tmp}) \cdot 7}{100}\right)$<br>with<br>$\text{tmp} = -\left(\min\left(115, \frac{ll_ari_bits}{10 \cdot (5 + 1)}\right) + 135\right)$ for $f_s = 96\,000$<br>$\text{tmp} = -\left(\min\left(115, \frac{ll_ari_bits_lb}{10 \cdot (5 + 1)}\right) + 135\right)$ for $f_s = 192\,000$ |

For lossless frames, this side information additionally comprises the lossless signalling fields specified in clause 5.10.2.1.14. The value of nbits is therefore reduced by the number of bits these fields occupy. Each field only when it is present according to clause 5.10.2.1.14: ll_adap_flag (1 bit), Shift Signal Bits (4 bits), fallback_mode (1 bit), b_relative (1 bit), off_idx (3 bits), BandDeltaBits (12 bits).

In case of ll_adap_flag == 0, the value of *nbits* is reduced by a value of max((nbytes << 3) >> 11), 2) bits as a safety margin.

For non-lossless (i.e. high-resolution) frames quantizedGainOff is calculated according to eq. 104 and lower bound to -181.

### 5.10.2.1.9 Deterministic curve and MSB/LSB separation

The deterministic curve separates the spectral values into two sets of bits planes (MSBs and LSBs), where the upper part of bits (MSB) is fed to the arithmetic coder and the lower part of bits (LSB) is residual coded. First, the inverse of the SNS scale factors (see eq (61)) are calculated by:

$$g_{sns_{inv}}(b) = \frac{1}{g_{sns}(b)} \; for \; b = 0 \; ... \; N_b - 1 \tag{217.7}$$

The inverted SNS coefficients $g_{sns_{inv}}(b)$ are then extended to a whole frame length $N_E$ (all spectral bins k) in a way similar to the spectral shaping described in clause 5.3.7.5:

```
for b=0 to N_b − 1 do
    for k=I_fs(b) to I_fs(b + 1) − 1 do
        g'_sns_inv(k) = g_sns_inv(b)
```

The inverted SNS coefficients are scaled by the global gain $gg$ to generate an envelope-like shape of the spectrum. The final deterministic curve $d(k)$ is obtained using additional log2 and ceil operations:

$$d(k) = \left\lceil log2\left(gg \cdot g'_{sns_{inv}}(k)\right)\right\rceil \; for \; k = 0 \ldots N_E - 1 \tag{217.8}$$

The MSBs are obtained removing the lower part of bits from the spectrum by performing a bitwise right-shift operation on the spectral values $X(k)$ with the values of the deterministic curve $d(k)$ as outlined in the following pseudo code:

```
for k=0 to N_E − 1 do
    if X(k) < 0:
        X_t(k) = -(|X(k)| ≫ d(k))
    else:
        X_t(k) = X(k) ≫ d(k)
```

The truncated spectrum $X_t(k)$ containing the MSB bitplanes is arithmetically coded (clause 5.10.2.1.11).

The LSB bitplanes are encoded by the residual coder (clause 5.10.2.1.12) and are obtained by disregarding the MSB bitplanes in $X(k)$, i.e. only bitplanes below the deterministic curve are considered for LSB encoding. The LSB part is encoded as described in clause 5.10.2.1.12.

The calculation of the deterministic curve and the MSB/LSB separation shall be implemented bit-exact in comparison to the C reference code.

The corresponding reference implementation is provided in source file deterministic_curve.c.

### 5.10.2.1.10 Deterministic curve for 192 kHz sampling rate and 24 bits per sample PCM input

For the input sampling rate of 192 000 Hz and 24 bits per sample , the deterministic curve is assembled by two different approaches. The spectral values are split into a low band and a high band, where the low band is modeled in the same way as described in clause 5.10.2.1.9 but with a reduced max band number. The inverse of the SNS scale factors for the low band are:

$$g_{sns_{inv}}(b) = \frac{1}{g_{sns}(b)} \; for \; b = 0 \; ... \; N_b - 13 \tag{217.9}$$

which are extended to the length of the corresponding max low band number $I_{f_s}(N_b - 12)$:

```
for b=0 to N_b − 13 do
    for k=I_fs(b) to I_fs(b + 1) − 1 do
        g'_snsinv(k) = g_snsinv(b)
```

The determinstic curve representing the low band of the spectrum is given by:

$$d_{lb}(k) = \left\lfloor log2\left( \; gg \cdot \; g'_{sns_{inv}}(k)\right)\right\rfloor \; for \; k = 0 \; ... \; I_{f_s}(N_b - 12) - 1 \tag{217.10}$$

The remaining part of the deterministic curve is determined by calculating the average bit usage of each individual high band as outlined in the following pseudo code:

```
for b=N_b − 12 to N_b − 1 do

    bandWidth = I_fs(b + 1) - I_fs(b);
    sumBitWidth = 0;

    for k=I_fs(b) to I_fs(b + 1) − 1 do
        BitWidth = 0;
        While( |X_t(k)| >> BitWidth ) > 0:
            BitWidth++;
        sumBitWidth += BitWidth;

    averBitWidth = sumBitWidth / bandWidth;
```

The 12 high bands of the deterministic curve are coded separately into the bitstream by using a 1 bit delta coding scheme extending the previous pseudo code to:

```
LastSegment = 0;
BandDeltaBits = 0;
counter = 0;

for b=N_b − 12 to N_b − 1 do

    bandWidth = I_fs(b + 1) - I_fs(b)
    sumBitWidth = 0;

    for k=I_fs(b) to I_fs(b + 1) − 1 do
        BitWidth = 0;
        While( |X_t(k)| >> BitWidth ) > 0:
            BitWidth++;
        sumBitWidth += BitWidth;

    averBitWidth = sumBitWidth / bandWidth;

    If( d(I_fs(b) − 1) ) == 0:
        LastSegment = 0;
```

```
Else if( b == N_b − 12 ):
    If( averBitWidth < d_lb(I_fs(b) − 1) ):
        BandDeltaBits(counter) = 1;
        LastSegment = d_lb(I_fs(b) − 1) − 1;
    Else:
        LastSegment = d_lb(I_fs(b) − 1);

Else:
    If( averBitWidth < LastSegment ):
        BandDeltaBits(counter) = 1;
        LastSegment--;

counter++;

//Create high band part of deterministic curve
for k=I_fs(b) to I_fs(b + 1) − 1 do
    d_hb(k) = LastSegment;
```

The final deterministic curve is composed by the low band part $d_{lb}$ and $d_{hb}$:

$$d(k) = \begin{cases} d_{lb}(k) & for\ k = 0 \dots I_{f_s}(N_b - 12) - 1 \\ d_{hb}(\mathrm{k}) & for\ k = I_{f_s}(N_b - 12) \dots \mathrm{N_e} - 1 \end{cases} \quad (217.11)$$

### 5.10.2.1.11 Arithmetic coding (clause 5.3.14.4)

#### 5.10.2.1.11.1 Introduction

For lossless frames, all the truncated spectral values $X_t(k)$ (i.e. the MSB part) are calculated as described in clause 5.10.2.1.9.

In case the ternary flag mixed_coding_flag is set to "-1", then the full truncated spectrum $X_t(k)$ is noiselessly encoded by the noiseless 2-tuple encoding part of the Arithmetic Encoder.

In case the ternary flag mixed_coding_flag is set to "0" or "1", the arithmetic coder will employ mixed 2-tuple and HPVC (Half Pyramid Vector Coding) noiseless arithmetic encoding of the tail of the truncated spectrum.

When the flag is "0", the nominal starting point for mixed arithmetic coding is 12 800 Hz and when the flag is "1" the nominal starting point is 16 000 Hz. When mixed coding is active, the coefficients prior to a final starting point are processed by the 2-tuple encoding part of the Arithmetic Encoder and the coefficients from the final starting point and up to ***lastnz*** are encoded according to clause 5.10.2.1.11.2.

#### 5.10.2.1.11.2 Mixed 2-tuple and HPVC encoding and signaling

The final starting point is first adjusted based on the nominal starting point and the available last encoded coefficient *lastnz*, so that an integer number of *Nsignal* length blocks may be encoded (*Nsignal*=64). At the final starting point and onwards a *NpIdx* codeword is signaled at possible *Nsignal* instances to convey the Mixed coding blocktype alternatives as described in Table 5.49.

**Table 5.49: Mixed coding blocktype alternatives**

| *NpIdx* | *Np* | Mixed coding blocktype alternative |
|---|---|---|
| 0 | 64 | Arithmetic 2-tuple coding of *Np/2* tuples according to clause 5.3.14.4 |
| 1 | 64 | HPVC-tree coding of *Np* coefficients according to clause 5.10.2.1.11.3 |
| 2 | 128 | |

The determination of what *NpIdx* to transmit at the possible *Nsignal* instances is based on an open loop L1-norm analysis of the truncated high band spectrum $X_t(k)$, followed by a closed loop bitrate verification versus the corresponding 2-tuple coding alternative for the same number of total coefficients.

#### 5.10.2.1.11.3 HPVC-tree coding and multiplexing

For *NpIdx*$\in$\{1,2\}, the blocktype codeword is followed by transmission of *Kp* $\in$ *{0, 1,… 36}*, where *Kp* is the L1-norm of the current $X_t(k)$ block of length *Np*.

If the *Kp* value is non-zero, the $X_t(k)$ coefficients in the block are transmitted as an HPVC-tree according to Table 5.50. In Table 5.50 square brackets "[ ]" indicate encoding using whole integer bits, while curly brackets "{}" indicate fractional encoding using the range encoder. In case *Kp* is zero no further indices require multiplexing.

**Table 5.50: HPVC-tree coding and multiplexing**

| ***HPVC Tree-type*** | **Nb. of headers** | **Nb. of header leaves** | **Nb. of leaves** | **HPVC-tree encoding multiplexing** |
|---|---|---|---|---|
| A: empty tree | 0 | 0 | 0 | { *Kp* } |
| *B*: single leaf | 0 | n/a | 1 | { *Kp* }, [ LS ], { Leaf } |
| C: header + leaves | 1 | *NsHdr* = 1 | *Ns*∈ *[3 ...16]* | { *Kp* },[LS ], [ splitRule ], { Hdr }, { $Leaf_0$, …$Leaf_{(Ns-1)}$ } |
| D: split-header+ leaves | 1 | *NsHdr* = 3 | | { *Kp* }, [ LS ], [ splitRule ], { $splitHdr, hLeaf_0, hLeaf_1, hLeaf_2$ }, { $Leaf_0$, …, $Leaf_{(Ns-1)}$ } |
| NOTE: The Leading Sign (*LS*) coding convention and each individual header and leaf encoding employ the MPVQ enumeration according to clause 5.3.7.3.3.8. | | | | |

The HPVC tree type {*A, B, C, D*} is initially determined based on the available *Np* and *Kp* values for the current *Np* long segment of $X_t(k)$, employing fixed HPVC splitrules for uniform leaf sub-segments. Subsequently an adaptive HPVC-tree *splitRule* is signaled to determine the final number of leaves *Ns* and the individual leaf widths**,** then the leading sign(*LS*), the headers(*Hdr*) and leaves(*hLeaf*, *Leaf*) are determined based on the coefficients in $X_t(k)$ . The header and leaf indices are constrained by the HPVC splitrules to have a maximum entropy of 31 bits each.

For the tree construction cases {C, D}, the amplitude of each header element is the L1-norm of the corresponding leaf's sub-segment, and the polarity of each header element is the leading sign of the sub-segment in $X_t(k)$. The polarity information is transferred from the leaf to the header, and subsequently prior to leaf MPVQ enumeration, the first non-zero element in the leaf's sub-segment is assigned a positive polarity, thus creating a half pyramid with an L1-norm given by the header element.

After each encoding of an HPVC-tree the 2-tuple context is updated based on the last four coefficients of the current $X_t(k)$ block, enabling that a switch to 2-tuples may be performed without losing efficiency.

Whenever *NpIdx is 0*, the blocktype codeword is followed by transmission of *Np/2* 2-tuples as described in clause 5.3.14.4.

The number of HPVC trees with a Kp value larger than 1 employed for high band coding are restricted by a hard limit at the decoder side, see Table 5.51, the encoder prunes away surplus trees before enumeration and multiplexing based on the estimated bit gain for each candidate HPVC-tree.

#### 5.10.2.1.11.4 Reference implementation

The corresponding reference implementation is provided in source files hpvc_enc_fx.c and ari_codec.c.

### 5.10.2.1.12 Residual coding (clause 5.3.12)

For lossless frames, the residual signal is not calculated as described in clause 5.3.12. Instead, the less significant bits (LSB) of the truncated spectral values $X_t$, i.e. the bits missing from the more significant number representation parts, namely the bit planes located below the deterministic curve $d(k)$ (see clause 5.10.2.1.9) are coded into a variable length information (the residual payload) that is appended to the arithmetic coder output.

A prioritization rule decides, based on the remaining bit budget, which LSBs of which spectral values are included in the variable length information when the budget is insufficient to carry all of them. The prioritization rule is selected per frame by the one-bit control information *b_relative* (see clause 5.10.2.1.14). This is done as follows:

- *b_relative* = 0 is the first prioritization rule: the absolute numeric weight (absolute bit plane index) is used as the highest-ranking prioritization criterion and the frequency (band index) as the second-ranking criterion.

- *b_relative* = 1 is the second prioritization rule: the relative numeric weight (distance from the per-band MSB/LSB split border given by $\mathrm{d(k)}$) is used as the highest-ranking prioritization criterion and the frequency as the second-ranking criterion.

The prioritization iteration operates at scale factor band granularity: in each step, it commits one additional LSB plane to the band that is currently highest in priority, and its cost (one data bit per bin plus, on the first plane assigned to a band, one sign bit per bin whose MSB part is zero) is subtracted from the remaining bit budget. The LSBs are raw coded, i.e. not entropy coded.

When the next plane of the currently considered band would exceed the remaining available bit budget (when running in CBR mode), allocation for that one last block switches from the coarse per-scalefactor-band granularity to a fine per-bin granularity: the first *binIdxSplit* bins of the band receive the additional plane, the remaining bins do not. *binIdxSplit* is derived deterministically from the remaining bit budget and, when the band is receiving its first plane, from the per-bin sign bit cost. The iteration then terminates.

The LSBs selected by the prioritization rule are written into the variable length information in per-coefficient ascending-frequency order. For each spectral value, a single per-coefficient sign bit is written first when the truncated value $X_t(k)$ is $\mathrm{zero}$. The selected bits of that coefficient are then written most-significant-first. The sequential order of bits in the variable length information is therefore decoupled from the priority order.

An example of both prioritization rules for the same configuration is given in Figure 5.18a. The example shows 8 spectral bins partitioned into 3 scalefactor bands with d_band = [2, 6, 4] and a bit budget of 29 LSB bits.

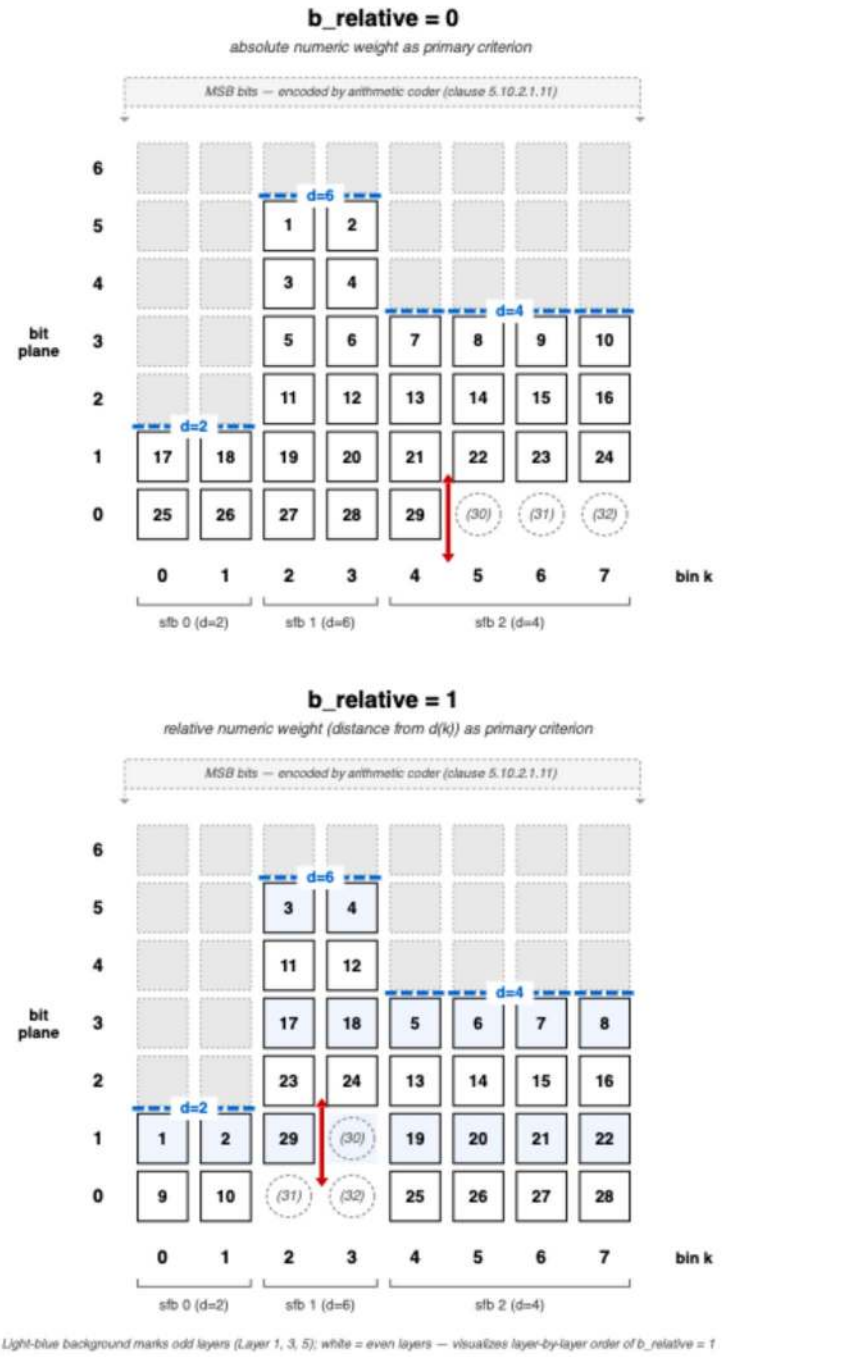

b_relative = 0
absolute numeric weight as primary criterion
MSB bits — encoded by arithmetic coder (clause 5.10.2.1.11)
bit plane
bin k
d=6
d=4
d=2
sfb 0 (d=2)
sfb 1 (d=6)
sfb 2 (d=4)
b_relative = 1
relative numeric weight (distance from d(k)) as primary criterion
Light-blue background marks odd layers (Layer 1, 3, 5); white = even layers — visualizes layer-by-layer order of b_relative = 1
Legend
Transmitted LSB bit (priority index n; lower = higher priority)
Omitted LSB bit (virtual priority index n; not in bitstream)
MSB region (encoded by arithmetic coder, clause 5.10.2.1.11)
MSB/LSB split given by d(k), per scalefactor band (5.10.2.1.9)
binIdxSplit: per-bin granularity for last partial-budget sfb
Example parameters
L_spec = 8 bins
max_sfb = 3
bands_offset = [0, 2, 4, 8]
d_band = [2, 6, 4]
budget = 29 LSB bits
Result: eff_det_curve[k]
b_relative = 0:
[2, 2, 6, 6, 4, 3, 3, 3]
b_relative = 1:
(both transmit 29 bits, omit 3)
[2, 2, 5, 4, 4, 4, 4, 4]
Note: per coefficient k with |x[k]| < 2^d(k), the first transmitted LSB bit is preceded by one sign bit in the bitstream (not visualized).

**Figure 5.18a**

Residual coding shall be implemented bit-exact in comparison to the C reference code. The corresponding reference implementation is provided in source file residual_coding_lossless.c (functions compute_resbits_priority(), compute_binIdxSplit() and residual_encoder_lossless()).

#### 5.10.2.1.13 Noise level estimation (clause 5.3.13)

Noise level estimation is deactivated for all lossless frames.

#### 5.10.2.1.14 Bitstream encoding (clause 5.3.14)

For the side information (clause 5.3.14.3) the following additional flags are present in the bitstream:

- ll_adap_flag: flag indicating if lossless (ll_adap_flag = 1) or high-resolution (ll_adap_flag = 0) coding is used for the current frame (see clause 5.10.2.1.15)
- fallback_mode: flag indicating if fallback mode (see clause 5.10.2.1.16) is enabled (for lossless frames only). Coding of WTDA buffer data sign bits (clause 5.10.2.1.16.2) starts from the next integer byte address i.e. six bits are padded.

NOTE: The flag "fallback_mode" in lossless context does not have any relation to the fallback operation referred to in Tables 5.2 and 5.2a.

- b_relative: 1 bit selecting the prioritization rule applied in residual coding (see clause 5.10.2.1.12). Present only for lossless frames with ll_adap_flag = 1 and fallback = 0.
- DeltaCodedBits: Bits representing the 12 highest bands of the deterministic curve; only transmitted for $f_s = 192\,000$ Hz and ll_adap_flag = 1 and 24 bits per PCM sample input format
- off_idx: quantized global gain offset parameter; only transmitted for $f_s \in [96\,000, 192\,000]$ and 24 bits per sample PCM input configuration, global gain offset is fixed for all other configs (for ll_adap_flag = 1 only). See Table 5.48 in clause 5.10.2.1.8.
- tns_lsb_remove: number of LSBs that are removed when using adaptive TNS for lossless frames (ll_adap_flag = 1), see Figure 5.18:
  - 1 bit to signal adaptive TNS (tns_lsb_remove > 0).
  - if adaptive TNS is on:
    - for 16 bits per sample PCM input: 2 bits for number of removed LSBs - 1 , allowing removal of up to 4 bit planes;
  - for 24 bits per sample PCM input: 3 bits for number of removed LSBs - 1, allowing removal of up to 8 bit planes.
- mixed_coding_flag: a ternary flag indicating the setup of the arithmetic coding of the highest bands. The first symbol ("-1") indicates that regular 2-tuple coding is applied for the frame. The second symbol ("0") indicates a low nominal starting point for the mixed arithmetic coding in the frame, finally a third symbol ("1") indicates a higher nominal starting point for the mixed coding. The mixed coding flag is only present for lossless frames with ll_adap_flag = 1 and fallback_mode = 0 and framing of 7,5 ms or 10 ms framing and a sampling frequency of 96 kHz or 192 kHz.
- Shift Signal Bits: An integer value consisting of four bits indicating the amount of bits the signal needs to be left-shifted at decoder side if the signal shift option is used.

The presence of the following parameter in the bitstream is conditional now, depending if the frame is lossless or in high-resolution mode:

- noise factor: only for high-resolution mode frames (ll_adap_flag = 0)

Bitstream encoding shall be implemented bit-exact in comparison to the C reference code.

The corresponding reference implementation is provided in source file enc_entropy.c.

#### 5.10.2.1.15 Dynamic Switching to High-Resolution mode

##### 5.10.2.1.15.1 Introduction

In case there is a bit rate restriction for encoding audio content (CBR mode), the encoder may not be able to perform lossless encoding of the audio content but instead switches to high-resolution encoding, making optimal use of the available bit budget. Apart from the decision made during adaptive TNS (if applicable, see clause 5.10.2.1.6) there is a secondary decision logic (lossless vs. high-resolution) which is described in the following subclauses. If no bitrate restrictions apply, the dynamic switching is not applicable as there is by definition sufficient bit rate budget for lossless coding at any time. This secondary decision logic is only executed if the primary (TNS) logic yields ll_adap_flag = 0.

##### 5.10.2.1.15.2 Estimation of bit usage

As there is a strong correlation between the spectral energy and the bit consumption required for encoding the frame, an estimation of the bit usage $N_{bu}$ can be performed based on eq (217.12) for $\boldsymbol{f_s}$ = 44,1 kHz or 48 kHz, eq (217.13) for $\boldsymbol{f_s}$ = 96 $kHz$ and eq (217.14) for $\boldsymbol{f_s}$ = 192 $kHz$:

$$N_{bu} = -3{,}152 \cdot 10^{-12} \cdot N_{ab}^4 + 7{,}027 \cdot 10^{-8} \cdot N_{ab}^3 - 4{,}951 \cdot 10^{-4} \cdot N_{ab}^2 + 2{,}406 \cdot N_{ab} - 88{,}05 \quad (217.12)$$

$$N_{bu} = 7{,}412 \cdot 10^{-9} \cdot N_{ab}^3 - 1{,}670 \cdot 10^{-4} \cdot N_{ab}^2 + 2{,}182 \cdot N_{ab} + 228{,}8 \quad (217.13)$$

where:

$$N_{ab} = \sum_{k=0}^{N_F-1} (\lfloor \log2(\max(1, |X_F(k)|)) \rfloor + 1) \quad (217.14a)$$

$$N_{bu} = 7{,}412 \cdot 10^{-9} \cdot N_{ab1}^3 - 1{,}670 \cdot 10^{-4} \cdot N_{ab1}^2 + 2{,}182 \cdot N_{ab1} + 228{,}8 + N_{ab2} \cdot 0{,}8 \quad (217.14b)$$

where:

$$N_{ab1} = \sum_{k=0}^{\frac{N_F}{2}-1} (\lfloor \log2(\max(1, |X_F(k)|)) \rfloor + 1)$$
$$N_{ab2} = \sum_{k=\frac{N_F}{2}}^{N_F-1} (\lfloor \log2(\max(1, |X_F(k)|)) \rfloor + 1) \quad (217.14c)$$

i.e. the aggregated amount of active bits (number of bits required to represent corresponding spectral value) in the spectral representation of the frame to be encoded. Note that trailing zeros in the spectrum are excluded from contributing to the calculation of active_bits, i.e. the summation ceases prematurely in this case.

##### 5.10.2.1.15.3 Decision on lossless vs. high-resolution coding mode

The flag *ll_adap_flag* indicates if a frame can be encoded in lossless mode, i.e. the bit budget is sufficient for lossless encoding (*ll_adap_flag* = 1) or needs to be encoded in high-resolution mode, i.e. the bit budget is not sufficient for lossless encoding (*ll_adap_flag* = 0) and is defined in equation (217.15):

$$\text{ll_adap_flag} = \begin{cases} 1 & \text{if } N_{bu} \leq nbits + bit_balance \\ 0 & \text{otherwise} \end{cases} \quad (217.15)$$

where *nbits* is defined in clause 5.2.5 and *bit_balance* is defined as

$$bit_balance = \begin{cases} N_F & for\ 16\ bits\ per\ sample\ PCM\ input, \\ 3 \cdot N_F & else. \end{cases} \quad (217.16)$$

#### 5.10.2.1.16 Fallback encoder

##### 5.10.2.1.16.1 General

The WTDA verbatim coding mode establishes a maximum upper bound on encoded data size and data rate for lossless operation and thus serves the purpose of a fallback mode. Therefore, WTDA verbatim coding shall be used if otherwise the payload size would exceed *fallback_num_bytes* as defined in equation 217.17:

$$\text{fallback_num_bytes} = \begin{cases} \left\lfloor \frac{17 \cdot N_F}{8} \right\rfloor & for\ 16\ bits\ per\ sample\ PCM\ input, \\ \left\lfloor \frac{25 \cdot N_F}{8} \right\rfloor & else. \end{cases} \quad (217.17)$$

In WTDA verbatim coding, the DCT-IV step shall be skipped and the WTDA signal data shall be directly encoded into the bitstream instead. The WTDA signal samples shall be coded as raw PCM according to clause 5.10.2.1.16.2.

##### 5.10.2.1.16.2 Encoding process

In case of fallback operation encoding shall consist of the following steps:

- Apply integer WTDA analysis (clause 5.10.2.1.3.2).
- Set fallback flag in bitstream (clause 5.10.2.2.1).
- Copy the resulting data from the WTDA analysis buffer as linear PCM data to bitstream:
  - For each WTDA buffer element (consisting of one sign bit and 16 magnitude bits for 16 bits per sample PCM input or 24 magnitude bits for 24 bits per sample PCM input):
    - Bit-wise write sign as single bit (1 for negative, 0 for positive) into side-information part of bitstream backwards, starting from next integer byte address (achieved by padding six zero bits).
    - Byte-wise write magnitude into bitstream forwards (least significant byte first, most significant byte last), i.e. two bytes for 16 bits per sample PCM input and three bytes for 24 bits per sample PCM input.

Hence, in fallback mode the side information part of the bitstream consists of only the following elements (in backward order):

- ll_adap_flag (1 bit)
- fallback_mode flag (1 bit)
- zero padding (six bits)
- signs of WTDA buffer elements ($N_F$ bits)

#### 5.10.2.1.17 Bitstream construction

For lossless frames the encoded data frame (see figure 5.12 in clause 5.5) is assembled from the contributing parts (arithmetic coded data, residual data, spectral data, side information) in two steps:

1) The gap between the forward part (arithmetic-coded data growing from the beginning of the frame) and the backward part (side information written in reverse from the end of the frame) is closed by copying (in a byte sense) the backward part directly behind the forward part. The variable *ll_totalBytes* denotes the resulting net byte count (forward part size + backward part size).

2) Further treatment depends on the selected rate mode:

   a) Variable bit rate (VBR) or constrained bit rate without padding (*ll_cbr* = 0) or padding option not selected): the actual encoded frame size reported to the transport layer is *ll_totalBytes*, i.e. each frame has only the length that is required to carry its compressed data.

b) Constrained bit rate with padding (*ll_cbr = 1* and padding option selected and *ll_adap_flag* = 1): the remaining frame positions from index *ll_totalBytes* up to *nbytes – 1* are filled with byte value *0x07*. The actual encoded frame size reported to the transport layer is *nbytes* , i.e. every frame has the same length irrespective of the lossless compression ratio.

NOTE: The byte value *0x07* can be unambiguously recognized as padding at the decoder side, because the last non-padding byte of the frame is guaranteed to have bit 7 set. Therefore the last non-padding byte is never smaller than *0x80*, and padding bytes *0x70* are always distinguishable from legitimate content bytes by a simple byte-value comparison.

Padding bytes shall not affect any tuning parameters that depend on the encoded bit rate. After the decoder has removed the padding pattern (see clause 5.10.2.2.1), the effective codec bit rate is derived from *ll_totalBytes* as for the unpadded case.

Bitstream construction shall be implemented bit-exact in comparison to the C reference code. The corresponding reference implementation is provided in source file enc_lc3plus.c.

## 5.10.2.2 Decoding process

### 5.10.2.2.1 Bitstream decoding (clause 5.4.2)

For lossless frames, before the side information (clause 5.4.2.3) can be parsed, the decoder shall remove any padding pattern written by the encoder (see clause 5.10.2.1.17). To do so, the variable *bp_side* is initialized to the index of the last byte of the frame (*bp_side = nbytes - 1*). In a while-loop, while the byte at position *bp_side* has the value of *0x07*, the value of *bp_side* is decremented by one. The loop stops at the first byte with a value different from *0x07*. This byte is treated as the last byte of the backward-written side-info region.

For the side information (clause 5.4.2.3) the following additional flags are decoded from the bitstream:

- ll_adap_flag: flag indicating if lossless (ll_adap_flag = 1) or high-resolution mode (ll_adap_flag = 0) coding is used for the current frame (see clause 5.10.2.1.15)

- fallback_mode: flag indicating if fallback mode (see clause 5.10.2.1.16) is enabled (for ll_adap_flag = 1 only) The decoding of the WTDA buffer data signs (clause 5.10.2.1.16.2) starts from the next integer byte address.

NOTE: The flag "fallback_mode" in lossless context does not have any relation to the fallback operation referred to in Tables 5.2 and 5.2a.

- b_relative: 1 bit indicating the prioritization rule to apply in residual decoding (see clause 5.10.2.2.5). Decoded only for lossless frames with ll_adap_flag = 1 and fallback = 0, otherwise set to 0 by default.

- BandDeltaBits: Bits representing the 12 highest bands of the deterministic curve; only transmitted for $f_s = 192\,000$ Hz and ll_adap_flag = 1 and 24 bits per PCM sample input format.

- off_idx: quantized global gain offset parameter; only transmitted for $f_s \in [96\,000, 192\,000]$ and 24 bits per sample PCM input configuration, global gain offset is fixed for all other configs (for ll_adap_flag = 1 only). See Table 5.48 in clause 5.10.2.1.8.

- tns_lsb_remove: number of LSBs that are removed when using adaptive TNS for lossless frames (ll_adap_flag = 1), see Figure 5.18:

  - 1 bit to signal adaptive TNS (tns_lsb_remove > 0).

  - if adaptive TNS is on:

    - for 16 bits per sample PCM input: 2 bits for number of removed LSBs, allowing removal of up to 4 bit planes;

    - for 24 bits per sample PCM input: 3 bits for number of removed LSBs, allowing removal of up to 8 bit planes.

- mixed_coding_flag: a ternary flag indicating the setup of the arithmetic coding of the highest bands. The first symbol ("-1") indicates that regular 2-tuple coding is applied for the frame. The second symbol ("0") indicates a low nominal starting point for the mixed arithmetic coding in the frame, finally a third symbol ("1") indicates a higher nominal starting point for the mixed coding. The mixed coding flag is only present for lossless frames with ll_adap_flag = 1 and fallback_mode = 0 and framing of 7,5 ms or 10 ms framing and a sampling frequency of 96 kHz or 192 kHz.

- Shift Signal Bits: An integer value consisting of four bits indicating the amount of bits the signal needs to be left-shifted at decoder side if the signal shift option is used.

The presence of the following parameter in the bitstream is conditional now, depending if the frame is lossless or coded in high-resolution mode:

- noise factor: only for high-resolution mode frames (ll_adap_flag = 0).

Bitstream decoding shall be implemented bit-exact in comparison to the C reference code.

The corresponding reference implementation is provided in source file dec_entropy.c.

#### 5.10.2.2.2 Fallback decoder

In case the fallback operation (see clause 5.10.2.1.16) is signalled by the fallback flag (see clause 5.10.2.2.1), decoding shall consist of the following steps:

- reading WTDA buffer elements samples from bitstream where each element consists of sign and magnitude: For each element:

  - Bit-wise read sign as single bit (1 for negative, 0 for positive) from bitstream backwards.

  - Byte-wise read magnitude from bitstream forwards (least significant byte first, most significant byte last), i.e. two bytes for 16 bits per sample PCM input and three bytes for 24 bits per sample PCM input and reconstruct WTDA buffer element from sign and magnitude.

- copy reconstructed data to the WTDA synthesis buffer (see clause 5.10.2.2.10.4) and apply integer WTDA.

#### 5.10.2.2.3 Deterministic curve and spectral recombination

In order to resynthesize the deterministic curve for LSB/MSB split (see clause 5.10.2.1.9) for lossless frames, the following steps are executed:

1) Extraction of global gain from decoded side information (see clause 5.4.2.3.1).

2) SNS scale factor decoding (see clause 5.4.7.2).

3) SNS scale factors interpolation (see clause 5.4.7.3).

4) Synthesis of deterministic curve from global gain and interpolated scale factors.

5) In case of fs = 192 000 Hz and ll_adap_flag = 1 the low bands of the deterministic curve are synthesized up to Nq – 13. The high bands are reconstructed by applying the decoded delta coded values.

This is executed only for lossless frames (i.e. ll_adap_flag = 1), else the deterministic curve is set to all zero.

The reference implementation for steps 4 and 5 above is provided in source file deterministic_curve.c.

The calculation of deterministic curve and spectral MSB and LSB recombination shall be implemented bit-exact in comparison to the C reference code.

#### 5.10.2.2.4 Arithmetic decoder (clause 5.4.2.7)

##### 5.10.2.2.4.1 Introduction

In case of a lossless frame with 96 kHz or 192 kHz with 7,5 ms or 10,0 ms operation, the ternary value mixed_coding_flag is decoded into one value out of {"-1","0","1"}, in all other operation cases the mixed_coding_flag is set to "-1".

In case the mixed_coding_flag is valued "-1", the first step is the arithmetic decoding process as described in clause 5.4.2.7, which is executed in order to obtain the MSB part of the spectral values. The truncated spectral values $X_t(k)$ (i.e. the MSB part) are calculated as described in clause 5.10.2.1.9.

In case the mixed_coding_flag is valued "0" or "1", the first step is mixed 2-tuple and HPVC decoding, and the truncated spectral values are obtained as described in clause 5.10.2.2.4.2.

In a second step the spectral MSB/LSB separation as described in clause 5.10.2.1.9 is inverted for lossless frames making use of the deterministic curve that was resynthesized as described in clause 5.10.2.2.3.

##### 5.10.2.2.4.2 HPVC-tree decoding and de-multiplexing

In case the ternary flag mixed_coding_flag is set to "0" or "1", the arithmetic coder will employ mixed 2-tuple and HPVC noiseless arithmetic decoding of the tail of the truncated spectrum.

When the mixed_coding_flag is "0", the nominal starting point for mixed arithmetic decoding is 12 800 Hz and when the flag is "1" the nominal starting point is 16 000 Hz. A final starting point is first set based on the nominal starting point and the available last encoded coefficient *lastnz*, so that an integer number of *Nsignal* length blocks may be decoded (*Nsignal*=64).

The coefficients prior to the final starting point are processed by the regular 2-tuple decoding part of the Arithmetic Decoder and the coefficients from the set final starting point and up to *lastnz* are decoded according to serial decoding of HPVC-tree indices.

At the final starting point and onwards an *NpIdx* codeword (see Table 5.49) is decoded at possible *Nsignal* instances, to establish the mixed coding blocktype for the next Np coefficients.

Whenever *NpIdx* is 1, the blocktype codeword is followed by *Np/2* 2-tuples, which are decoded as in clause 5.4.2.7.

When *NpIdx* is 1or 2 then 64 or 128 coefficients respectively, are decoded by demultiplexing an HPVC symbol and bit stream according to Table 5.50. The HPVC-decoding initially determines an HPVC tree type based on the ***Np*** value and the received ***Kp*** value. Subsequently the decoding routine selectively applies a fixed rule or a decoded ***splitRule*** to determine the final number of headers and leaves ***Ns***. The encoder multiplexing order made HPVC headers and split headers available prior to the dependent leaves in the serial stream, enabling a causal HPVC-decoding. Header and leaf leading signs and MPVQ-indices are obtained from the range decoder and then converted to spectral coefficients in $X_t(k)$ by employing the MPVQ de-enumeration routines, see clause 5.4.7.2.3.2.

After each decoding of a HPVC-tree the 2-tuple context is updated based on the last four coefficients of the last decoded $X_t(k)$ block, enabling that a switch to 2-tuples may be performed in synchronization with the encoder.

To allow for deterministic sink side decoding resources, the maximum number of HPVC trees to decode are restricted by a hard limit. The number of tree limit only applies to HPVC-trees with an L1-norm(***Kp*** value) larger than 1. The HPVC-tree decoding limit is a function of the sampling rate and the frame duration, see Table 5.51.

**Table 5.51: HPVC-tree decoding limits**

| Frame duration (ms) | Sampling frequency (kHz) | HPVC-tree decoding limit (number of trees) |
|---|---|---|
| 7,5 | 96 | 6 |
| 7,5 | 192 | 3 |
| 10,0 | 96 | 7 |
| 10,0 | 192 | 4 |

#### 5.10.2.2.4.2 Reference implementation

The corresponding reference implementation is provided in source files hpvc_enc_fx.c and ari_codec.c.

### 5.10.2.2.5 Residual decoder (clauses 5.4.2.8 and 5.4.3)

For lossless frames, the less significant bit part of the spectral values is obtained by inverse application of the operation described in clause 5.10.2.1.12. The residual decoding process as described in clause 5.4.3 is only executed for high-resolution mode frames (ll_adap_flag = 0).

The decoder reads the one-bit control information *b_relative* from the side-info region (see clause 5.10.2.2.1) and then reruns the same prioritization iteration that the encoder applied: same deterministic curve (clause 5.10.2.2.3) , same remaining bit budget after arithmetic decoding and side-info parsing, and same per-band zero-MSB count. All inputs to the iteration are identical on both sides, so the decoder obtains the same per-band number of transmitted planes (coarse per-scalefactor-band granularity) and, for the last block, the same *binIdxSplit* (fine per-bin granularity) without any additional side information.

The variable length information is then read in per-coefficient ascending-frequency order. For each spectral value, a per-coefficient sign bit is read first when the truncated value $X_t(k)$ is zero. The less significant bits of that coefficient are then read most-significant-first and combined with the truncated value to reconstruct the full integer value.

Residual decoding shall be implemented bit-exact in comparison to the C reference code. The corresponding reference implementation is provided in source file residual_coding_lossless.c (functions compute_resbits_priority(), compute_binIdxSplit() and residual_decoder_lossless()).

If TNS coding was not applied in the encoder for the frame under consideration, the reconstructed spectral representation undergoes a mid-rise quantizer in order to reestablish the correct energy level.

In order to achieve this, the reconstructed spectral values are adapted as follows:

1) Determine spectral indices (ind) with spectral values ≠ 0.
2) Determine m as difference original deterministic curve – modified deterministic curve as returned by function compute_resbits_priority().
3) For indices (ind) with spectral values ≠ 0 and m > 0:
   a) Add $2^{-1} - 1$ if the corresponding spectral value is > 0.
   b) Subtract $2^{m-1} - 1$ if the corresponding spectral value is < 0.

The corresponding reference implementation is provided in source file properRounding_fx.c.

### 5.10.2.2.6 Noise filling (clause 5.4.4)

Noise filling is not executed for lossless frames.

### 5.10.2.2.7 Application of global gain (clause 5.4.5)

The global gain is not applied for lossless frames, but has influence on the resynthesis of the deterministic curve (see clause 5.10.2.2.3).

### 5.10.2.2.8 SNS decoder (clause 5.4.7)

SNS shaping is not applied for lossless frames. For $N_{ms}$ = 1,25 ms, the Low Rate SNS scale factor decoding according to clause 5.4.7.2a shall be applied. For all other frame durations, the SNS scale factor decoding according to clause 5.4.7.2 shall be applied. The decoded and interpolated SNS data is used for resynthesis of the deterministic curve (see clause 5.10.2.2.3).

#### 5.10.2.2.9 TNS decoder (clause 5.4.6)

For lossless frames, TNS works as a predictor, improving the lossless coding gain, while TNS in the high-resolution mode is a perceptual tool, improving the audio quality especially for lower bitrate.

TNS decoding shall only be applied if TNS encoding had been applied in the encoding process (see clause 5.10.2.1.6) as signaled in the bitstream (see clause 5.4.2.3). The TNS parameters are identical compared to the high-resolution mode.

For lossless frames, the TNS filter might be applied on a precision reduced spectral data as indicated by tns_lsb_num_remove (see decoder side information). The TNS filter shall be applied according to clause 5.4.6 where the filtering operation IIRlattice() shall be bit-exact as provided in corresponding reference implementation source file tns_decoder_fx.c.

If tns_lsb_num_remove is greater than zero, the filtered spectral data shall be left shifted by tns_lsb_num_remove bits. and the LSB initialized with zeros. Afterwards, the spectral data is combined with the residual signal decoded from the bitstream representing the missing LSB data of the spectrum. The residual data shall be determined using clause 5.10.2.2.5.

Figure 5.19 outlines the TNS decoding process for lossless frames.

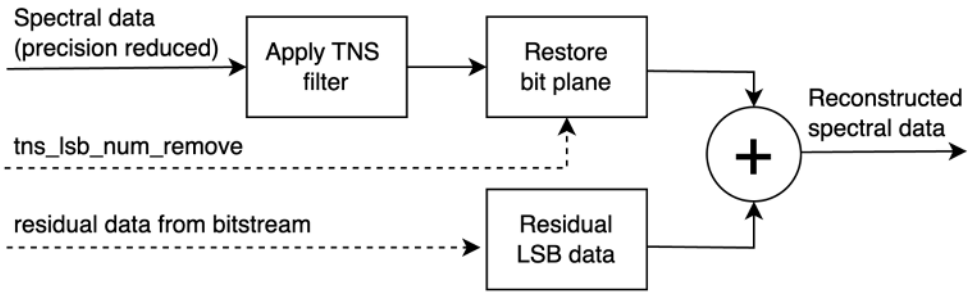

**Figure 5.19: TNS decoder for lossless frames**

#### 5.10.2.2.10 Low Delay MDCT synthesis (clause 5.4.8)

##### 5.10.2.2.10.1 Overview

The low delay MDCT shall be implemented for the lossless path by using an inverse integer DCT-IV stage and an inverse integer Windowing – Time Domain Aliasing stage (WTDA) stage. The high-resolution path shall be implemented using a regular DCT-IV stage followed by inverse WTDA stage without rounding.

The MDCT synthesis is fully compatible with the Low Delay MDCT of the high-resolution mode and therefore, only one set of window coefficients is required.

The lossless path shall be implemented using a lifting scheme with rounding which allows to stay in the integer domain. Each stage shall be implemented bit-exact in comparison to the C reference code. Therefore, the exact window coefficients, rounding and scaling operations of the fixed-point code need to be preserved.

For the high-resolution path a floating point representation shall be used.

5.10.2.2.10.2 Inverse integer DCT-IV stage

The integer DCT-IV shall be applied whenever ll_adap_flag is 1, i.e. for lossless frames. The decomposition into lifting steps for implementing the inverse integer DCT-IV of length *N* is defined in the following way:

$$DCTIV_N^{-1} = P^{-1}Q^{-1}\begin{pmatrix} I & 0 \\ -I & I \end{pmatrix}\begin{pmatrix} I & \frac{1}{2}I \\ 0 & I \end{pmatrix}\begin{pmatrix} I & -\frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix}\begin{pmatrix} I & 0 \\ \sqrt{2}DCTIV_{N/2} & I \end{pmatrix}$$
$$\begin{pmatrix} I & -\frac{1}{2}\sqrt{2}DCTIV_{N/2} \\ 0 & I \end{pmatrix}\begin{pmatrix} 1 & & & & -cs(0) \\ & \ddots & & \iddots & \\ & & 1 & -cs(N/2-1) & \\ & & & 1 & \\ & & & & \ddots \\ & & & & & 1 \end{pmatrix}$$
$$\begin{pmatrix} 1 & & & & \\ & \ddots & & & \\ & & 1 & & \\ & & -s(N/2-1) & 1 & \\ & \iddots & & & \ddots \\ -s(0) & & & & & 1 \end{pmatrix}\begin{pmatrix} 1 & & & & -cs(0) \\ & \ddots & & \iddots & \\ & & 1 & -cs(N/2-1) & \\ & & & 1 & \\ & & & & \ddots \\ & & & & & 1 \end{pmatrix}\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \quad (217.17a)$$

The coefficients for the inverse DCT-IV stage are defined in clause 5.10.2.1.3.2. Each lifting step contains a multiplication of the input signal with floating point coefficients, a linear combination and a rounding operation to Q31. The bit-exact reference implementation is provided in intDCT_fx.c including the FFT implementations in fft.c.

5.10.2.2.10.3 DCT-IV stage

To minimize complexity, the DCT-IV shall be used for the High-Resolution audio path, which is defined by:

$$\hat{y}(n) = \sum_{k=0}^{N_F-1} \hat{X}(k) \cos\left[\frac{\pi}{N_F}\left(n+\frac{1}{2}\right)\left(k+\frac{1}{2}\right)\right] \quad for \;\; n = 0 \ldots N_F - 1 \qquad (217.18)$$

Where $\hat{y}(n)$ is the aliased time signal and $\hat{X}(k)$ is the vector of spectral coefficients.

5.10.2.2.10.4 Inverse integer WTDA stage

The integer WTDA stage shall be applied whenever ll_adap_flag is 1, i.e. for lossless frames. The integer WDTA combines the windowing operation and the time domain aliasing operation. The decomposition into lifting steps for implementing the WTDA synthesis stage is illustrated by Figure 5.20, where x(k) with k=0...$N_F$/2-1 are the reconstructed integer audio samples of the current block. A negative index indicates samples from the previous block. Each lifting step contains a multiplication of the input signal with floating point coefficients, a linear combination and a rounding operation to Q31.

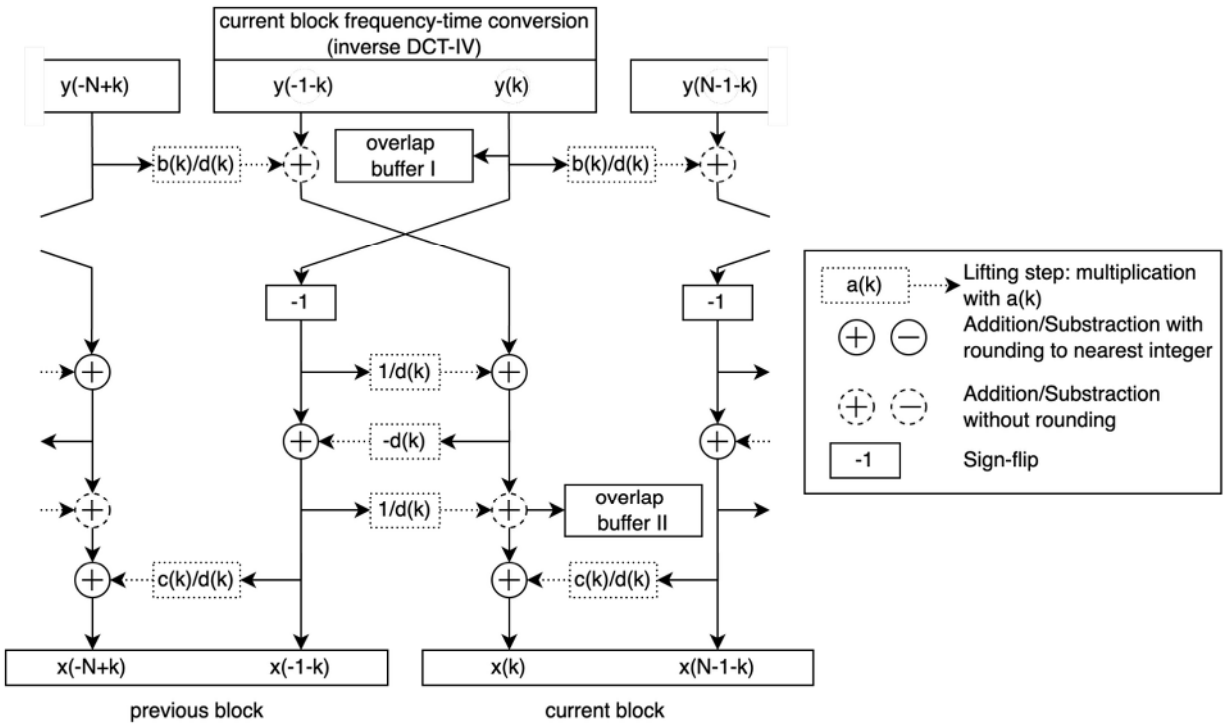

**Figure 5.20: Detailed description of WTDA synthesis stage**

The vector [y(-1-k) y(k)] is the time domain output to the DCT-IV stage, which conducts the time-frequency conversion. a(k), b(k), c(k), d(k) are portions of window coefficients defined by: a(k) = w($N_F$-1-k), b(k) = -w(k), c(k) = w($2N_F$-1-k), d(k) = w($N_F$+k), with w(j) for j = 0, …, $2N_F$-1 denoting the analysis high-resolution window coefficients, see clause 5.8.2. The windows have typically an asymmetric shape with a leading zero section of Z samples. As Z is part of c(k), the last lifting step can partly be omitted. In each lifting step, the floating-point coefficients are multiplied with the corresponding input value, followed by a linear combination and depending on whether a second lifting step is applied to the signal path, a rounding operation to the nearest integer in format Q31 is applied. Therefore, at any stage the signal is represented as integer numbers.

The overlap-add buffer consists of two segments where the overlap buffer II stores an intermediate (non-rounded / floating-point) signal in Q33.

The bit-exact reference implementation is provided in file intDCT_fx.c.

#### 5.10.2.2.10.5 Inverse WTDA stage

The inverse WTDA stage shall be applied whenever ll_adap_flag is 0, i.e. for high-resolution frames. The inverse WTDA stage shall be implemented according to clause 5.10.2.2.10.4 but without any rounding operation to integer numbers which increases precision and minimizes complexity. The value format can therefore be considered as floating point.

#### 5.10.2.2.10.6 Overlap conversion

In order to combine the decoded lossless representation and the high-resolution representation within the overlap-add operation in the WTDA, the overlap-add buffers require some scaling operation.

Whenever in the previous frame ll_adap_flag was 1 and ll_adap_flag is 0 in the current frame, the overlap buffer needs to be scaled to the used Q format of the spectral data in the current frame.

Whenever in the previous frame ll_adap_flag was 0 and ll_adap_flag is 1 in the current frame, the overlap buffer I shall be scaled to Q31 with rounding and the overlap buffer II needs to be scaled to Q33 with rounding.

If a shift value is transmitted, it shall be added to the overlap buffer's scaling parameter during the overlap conversion to reach the target Q format whenever ll_adap_flag transitions between frames (0 in the previous frame and 1 in the current frame, or 1 in the previous frame and 0 in the current frame).

If ll_adap_flag is 1 in both the previous and the current frame and the transmitted shift value differs from the previous frame's value, the overlap-add memory needs to be shifted by the difference between the two shift values. If the current frame's shift value is higher, the memory is right-shifted by delta = current_shift_value − previous_shift_value. If the previous frame's value is higher, it is left-shifted by delta = previous_shift_value − current_shift_value.

#### 5.10.2.2.11 Long Term Postfilter (clause 5.4.9)

The Long-Term Postfilter (LTPF) is deactivated for lossless frames (ll_adap_flag = 1).

#### 5.10.2.2.12 Output scaling

For high-resolution frames (ll_adap_flag = 0), the floating point output of the inverse WTDA stage shall be denormalized (i.e. brought to integer format) and shifted to the correct PCM bits per sample resolution (16 or 24, to be signalled out-of-band), rounding and saturation shall be applied.

For lossless frames (ll_adap_flag = 1), no output scaling shall be applied, as the MDCT synthesis is purely based on integer representation of the data.

If a shift value > 0 is transmitted, the samples of the current frame are left-shifted by the shift value.

### 5.10.2.3 General

Clause 5.2.2: The sampling rate index 6 is added for audio sampling frequency 192 kHz.

# 6 Source code description

## 6.1 Overview

This clause gives an overview of the reference C code included in archive ts_103634v010701p0.zip which accompanies the present document.

The ANSI-C codec has been verified on the following systems:

- PC compatible computers with Visual C++ compiler, 32-bit builds.
- PC compatible computers with:
  - GCC compiler version 4.9.2 (Debian™ 4.9.2-10+deb8u1), 64-bit builds.
  - GCC compiler version 6.3.0 (Debian™ 6.3.0-18+deb9u1), 64-bit builds.

NOTE: Debian is a trademark owned by Software in the Public Interest, Inc.

  - clang version 6.0.0, 64-bit builds.
- PC compatible computers with LLVM compiler version 9.0.0, 64-bit builds.

## 6.2 Contents of the C source code

The C code is organized as follows.

**Table 6.1: Source code directory structure**

| Directory | Description |
|---|---|
| README.txt | Compile instructions, feature list, command lines |
| src/fixed_point | Project files for fixed point code |
| src/floating_point | Project files for floating point code |
| testvec | Test vector package: MD5 hashes for fix-point and floating-point reference code |
| testvec/input | Input PCM Files |
| conformance | Conformance package: conformance script and tools |
| helper tool | Some scripts for simulating applications |
| fec_control_unit | Implementation of FEC control unit example from Annex C |

The fixed-point as well as the floating-point project contain a makefile and a Visual Studio MSVC file for compilation. Once the software is compiled, this directory will contain a compiled version of the codec with the name LC3plus. More information is provided in the Readme.txt file contained in archive ts_103634v010701p0.zip which accompanies the present document.

## 6.3 File formats

### 6.3.1 Sound file (encoder input and decoder output)

Speech files use the Wave file format [i.3] with either 16 or 24 bits per sample. The encoder input Wave file defines the sampling frequency that will be used by the encoder. The byte order depends on the host architecture, e.g. least significant byte first on PCs.

### 6.3.2 Switching profile (encoder input)

The encoder program can read in a switching profile which specifies the encoding parameter that will be used for each audio frame. The profile consists of a binary file of little-endian 64-bit values, where each value represents a frame's parameter. If the switching file is shorter than the input, it will be looped from the beginning.

Possible parameters for switching files are bit rate in bps, bandwidth in Hz or ep class in class · 100.

### 6.3.3 Parameter bitstream file (encoder output and decoder input)

The LC3plus software supports the G.191 bit stream format [i.4] and therefore, the bit stream can be manipulated with the STL error insertion devices. For a correct decoder initialization, the encoder writes an additional configuration file which is provided to the decoder. The configuration contains information on sampling rate, number of channels and usage of channel coder.

## 6.4 Test vector package

The test vector package verifies the compilation of the reference fixed-point and floating-point source code and that the resulting executables run as expected on a dedicated platform with bit-exact results. This is a pre-requisite for the conformance tests (see clause 7) where an implementation under test is compared to these reference executables.

The test vector package shall not replace the conformance tests. For testing an implementation with bit-exact behaviour, the conformance test and the RMS metric should be used.

The package contains:

- Seven input PCM audio files sampled at 8 kHz, 16 kHz, 24 kHz, 32 kHz, 44,1 kHz, 48 kHz and 96 kHz.
- Two text files containing the pre-calculated MD5 hashes of the configurations stated in Table 6.2.

The files are located according to Table 6.1.

In order to verify the correct compilation, the user shall compile the source code in the 'src' folder and run the script via 'perl testvecCheck.pl'. The script will create bitstreams and decoded PCM files with the test executable and compare the MD5 hashes of the output files with the pre-calculated hashes. If all hashes match, the test is passed. If at least one MD5 hash differs, the test is considered as failed. The result is printed in the console after the script has finished.

**Table 6.2: Supported Configurations**

| Sampling rate [kHz] | Bit rate [kbit/s] | EP Mode [0 = off, 4 = highest protection] |
|---|---|---|
| 8 | 32 | 0, 4 |
| 16 | 32 | 0, 4 |
| 24 | 48 | 0, 4 |
| 32 | 48 | 0, 4 |
| 44,1 | 64 | 0, 4 |
| 48 | 64 | 0, 4 |

# 7 Conformance

## 7.1 Overview

The conformance procedure shall be applied to verify the quality of LC3plus encoder and decoder implementation. It allows testing of implementation with a non-bit-exact behaviour compared to the fixed-point reference executable. Given that, floating-point implementations can also be verified.

Clause 7.2 describes the test framework and specifies several quality metrics (clause 7.2.4) which can assess the quality of the implementation.

Clause 7.3 defines several conformance tests grouped into core coder tests (clause 7.3.2), concealment tests (clause 7.3.3) and channel coder tests (clause 7.3.4). Most of the tests can be conducted by the modules (encoder, decoder and codec) (clause 7.2.3) separately.

Clause 7.4 specifies which quality metric shall be used for a dedicated conformance test and which modules shall be tested separately.

Clause 7.5 defines the criteria for considering an implementation as conformant.

Clause 7.7.2 gives an example for specifying conformance for specific applications.

The conformance scripts include a reference implementation of the item preparation, core coder test, packet-loss tests and the channel coder tests.

## 7.2 Test framework

### 7.2.1 Test material

A selection of nine items from the European Broadcasting Union Sound Quality Assessment Material EBU SQAM CD [7] shall be used. The material ensures testing of a wide range of LC3plus features. These items are trimmed according to Table 7.1.

**Table 7.1: LC3plus Conformance Test Items**

| Track Name | Track Number | Start [s] | Fragment Length [s] | Used in PLC test |
|---|---|---|---|---|
| ABBA | 69 | 7 | 8 | YES |
| Castanets | 27 | 0 | 8 | YES |
| Eddie_Rabbitt | 70 | 0 | 8 | NO |
| Female_Speech_German | 53 | 0 | 8 | YES |
| Glockenspiel | 35 | 0 | 10 | NO |
| Harpsichord | 40 | 39 | 9 | YES |
| Male_Speech_English | 50 | 0 | 8 | YES |
| Piano_Schubert | 60 | 0 | 8 | NO |
| Violoncello | 10 | 0 | 10 | NO |

For all items, a fade-in of 0,5 s and a fade-out of 0,7 s is chosen. The exact command lines used for pre-processing the test items are provided in the LC3plus Conformance Script (clause 7.2.5.6). Note that a subsection of these items is used for the PLC and channel coder tests.

## 7.2.2 Test permutations and codec parameters

The input items in combination with the codec parameters, e.g. bit rates, sampling rates, frame sizes, are permutated in order to create a set of test conditions. These permutated test conditions are used for each test unless stated otherwise.

For the channel coder tests, the parameters are in addition permutated with the five Error Protection (EP) modes (0, 1, 2, 3, 4).

For LC3plus tests under the lossless mode (clause 7.3.8), the parameters are in addition permutated with the supported bit depths (16-bit and 24-bit). The codec parameters depend on the application under test, e.g. 16 kHz sampling rate and bit rate 32 kbit/s for regular WB voice calls.

## 7.2.3 Modules under test

The conformance is applied for the following modules. Each module test creates two audio files which are further analysed by quality metrics in order to compare module under test and reference:

- Encoder under Test (EuT): Items are encoded with the EuT and the Reference Encoder (ER) at all permutations and decoded with the Reference Decoder (DR).
- Decoder under Test (DuT): Items are encoded with the ER at all permutations and decoded with the DR and DuT.
- Encoder-Decoder (EncDec): Items are encoded with the EuT and decoded with the DuT as well as encoded with the ER and decoded with the DR.

The reference executables/modules (DR and ER) shall be compiled without any modification of the reference source code and shall pass the test vector check outlined in clause 6.4.

## 7.2.4 Quality metric calculation

### 7.2.4.1 Root Mean Square

The RMS metric compares two time-domain signals and calculates its similarity in accuracy. The RMS level is calculated as follows:

$$RMS = \sqrt{\frac{1}{N}\sum_{n=1}^{N}\left(Out(n) - Ref(n)\right)^2} \tag{218}$$

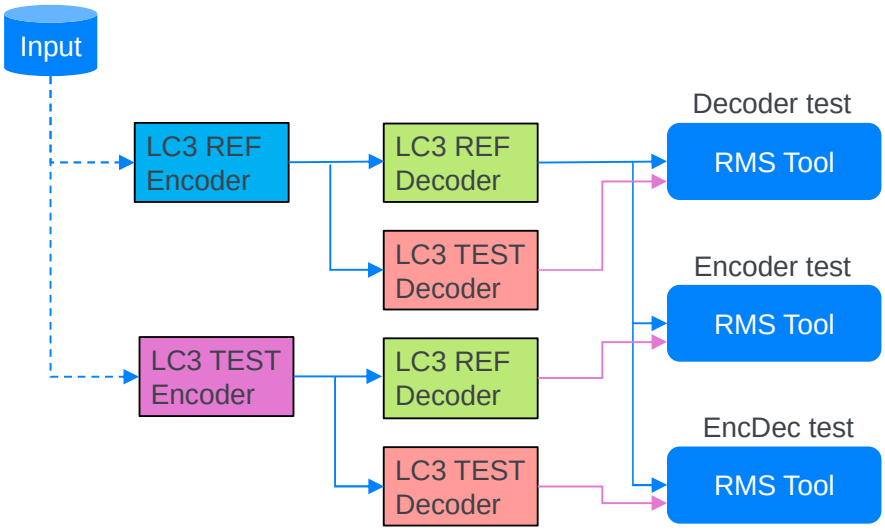

where *Out*(n) denotes output signal under test, and *Ref*(n) denotes the reference signal for the comparison.

To fulfil the RMS/LSB Measurement test at an accuracy level of K bits, an LC3plus encoder and decoder shall provide an output waveform such that the RMS level of the difference signal between the output of the decoder under test and the output of the reference decoder is less than $\frac{1}{2^{K-1} \cdot 12^{0,5}}$. In addition, the difference signal shall have a maximum absolute value ($RMS_{max.abs.diff}$) below a certain threshold.

An RMS tool implementation is provided within the LC3plus conformance script package as C source code. This code can be compiled and the executable can be used to compare two audio files and calculate the overall RMS in dB, with the maximum absolute difference of two audio samples and the reached RMS criterion expressed in bits. The RMS tool can be used with the following command line:

./rms file1.wav file2.wav [k]

where *k* is an optional parameter to set the conformance threshold in bits. Figure 7.1 illustrates the process and the calculation of the RMS value.

NOTE: RMS might not be applicable for testing encoder implementations operating on different platforms, e.g. floating point. In that case Delta ODG is recommended.

**Figure 7.1: RMS calculation procedure for Encoder, Decoder and EncDec tests**

### 7.2.4.2 Delta ODG value

To calculate the Objective Difference Grade (ODG) between two audio files, Recommendation ITU-R BS.1387-2 [i.11] (Advanced) implementation shall be used. The "Method for objective measurements of perceived audio quality" (Recommendation ITU-R BS.1387-2 [i.11] (Advanced)) algorithm executable calculates the ODG between a coded audio file and the reference audio file. The ODG value is calculated for two files for each test permutation:

- ODG between reference audio and coded audio using LC3plus Reference codec
- ODG between reference audio and coded audio using LC3plus codec under test

The difference between the two ODGs ($\Delta_{ODG}$) shall not exceed a certain threshold according to clause 7.2.4.4. Figure 7.2 illustrates the coding process and the calculation of $\Delta_{ODG}$ for Encoder and EncDec Tests.

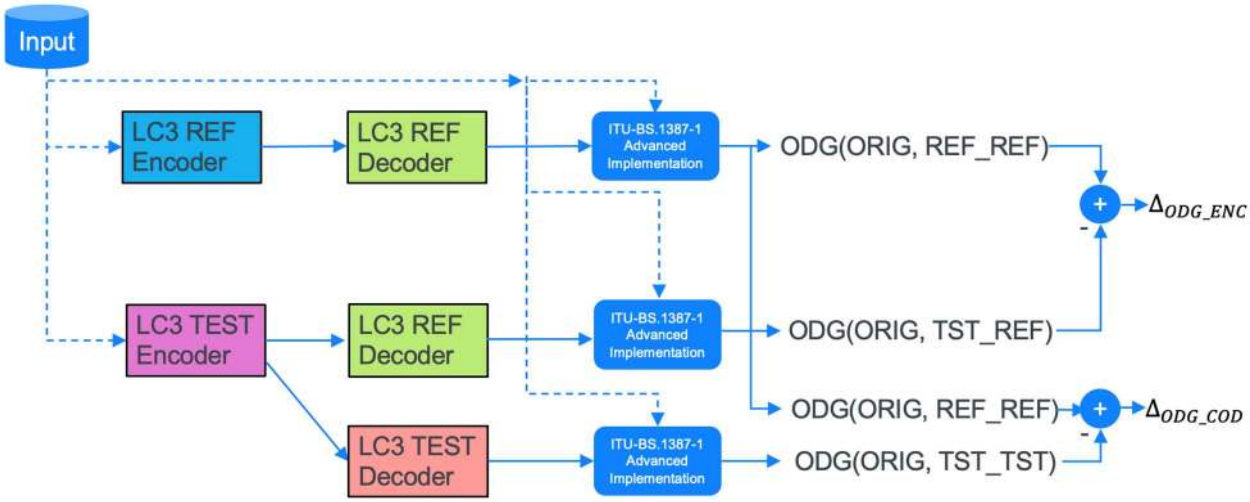

**Figure 7.2: $\Delta_{ODG}$ calculation procedure for Encoder and EncDec tests**

### 7.2.4.3 Maximum Loudness Difference (MLD)

The MLD value is calculated for two decoded files for each test permutation according to [i.7]. The following steps according to Recommendation ITU-R BS.1387-2 [i.11] need to be processed first:

- Filterbank (Annex 2, clause 2.2.5 of [i.11]):
  - subsample factor F changed to 16 for higher time resolution.
- Outer and Middle Ear Filtering (Annex 2, clause 2.2.6 of [i.11]).
- Frequency Domain Smearing (Annex 2, clause 2.2.7 of [i.11]).
- Rectification (Annex 2, clause 2.2.8 of [i.11]).
- Time Domain Smearing 1 - Backward Masking (Annex 2, clause 2.2.9 of [i.11]).
- Adding of Internal Noise (Annex 2, clause 2.2.10 of [i.11]).
- Time Domain Smearing 2 - Forward Masking (Annex 2, clause 2.2.11 of [i.11]).
- Loudness (Annex 2, clause 3.3 of [i.11]):
  - This clause defines the specific loudness patterns $N[k,n]$ for $k$ subbands and $n$ time samples.
  - The specific loudness patterns are calculated for:
    - reference signal $N_{ref}[k,n]$
    - signal under test $N_{test}[k,n]$

Maximum Loudness Difference (MLD):

- The loudness difference $N_{diff}[n]$ is calculated as follows:

$$N_{diff}[n] = \sum_{k=1}^{40} \left| N_{ref}[k,n] - N_{test}[k,n] \right| \quad (218a)$$

- he Maximum Loudness Difference (MLD) for this item is then the maximum over all $n$ time samples. Note that $n$ has a granularity of 2 ms:

$$\mathrm{MLD} = \max\left(N_{diff}[n]\right) \quad (218b)$$

The MLD tool C source code is provided within this conformance package. Figure 7.3 illustrates the coding process and the calculation of the MLD value.

The MLD tool can be used with the following command line:

*./mld file1.wav file2.wav*

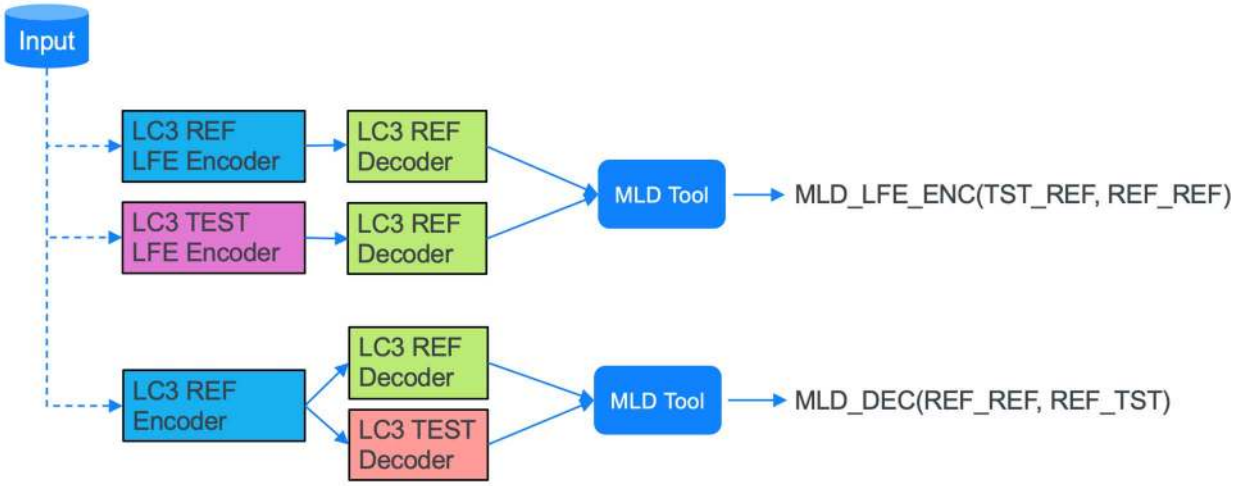

**Figure 7.3: Calculation procedure of MLD for encoder LFE and decoder concealment/error protection tests**

### 7.2.4.4 Thresholds

See clause 7.5.

## 7.2.4a Lossless metric calculation

### 7.2.4a.0 General

Under lossless mode operation of LC3plus, additional metrics shall be computed using the bitstream analyser (clause 7.2.5.7).

### 7.2.4a.1 Delta Compression

The efficiency of the lossless operation of the codec is measured by the average compression ratio. This metric quantifies the reduction in data bytes achieved by the lossless encoding process relative to the raw PCM bitrate. It is calculated as the ratio of the average compressed payload rate to the uncompressed PCM rate.

$$Average\ Compression = \frac{8\,000 \cdot nBytes_{total}}{(nChannels \cdot f_s \cdot bps \cdot N_{frames} \cdot frame_{ms})} \quad (218c)$$

where $nBytes_{total}$ are the total data bytes used for encoding across all frames, excluding the padded data bytes (see clause 7.3.8 for padding), $nChannels$ is the number of audio channels, $f_s$is the sampling rate, $bps$ is the bit depth or bits per sample (e.g. 16 or 24), $N_{frames}$ $is$ the total number of frames and $frame_{ms}$ is the frame size.

Delta compression is calculated for two audio files using the bitstream analyser (clause 7.2.5.7) which indicates any difference in the compression ability compared to the reference.

### 7.2.4a.2 Delta Percentage of Lossless Samples

Another metric for measuring the efficiency of the lossless operation is checking the percentage of lossless samples. This metric quantifies the proportion of decoded samples that are bit-exact to the original input samples.

The percentage of lossless samples is then calculated as:

$$\text{Lossless Samples (\%)} = \frac{N_{\text{total}} - N_{\text{non-lossless}}}{N_{\text{total}}} \times 100 \quad (218d)$$

where $N_{total}$ is the total number of audio samples across all channels and $N_{non\text{-}lossless}$ is the number of samples whose decoded value differs from the corresponding input sample (i.e. not bit-exact).

Difference in the percentage of lossless samples is calculated for two audio files using the bitstream analyser (clause 7.2.5.7) which indicates any difference in the lossless operation compared to the reference.

#### 7.2.4a.3 Thresholds

See clause 7.5a.

### 7.2.5 Software and tools

#### 7.2.5.1 Gen_rate_profile

This tool can be used to create switching files:

*gen_rate_profile -layers A, B, C, … SWF_FILE period*

where A, B, C are the values which should be switched (e.g. bitrates or error protection modes), SWF_FILE is the generated switching profile and period the number of frames between switching points.

NOTE: For error protection switching files, the error protection mode is multiplied with a value of 100 in order to operate this tool.

#### 7.2.5.2 Eid-xor

This tool can be used to introduce bit errors to a G.192 bitstream:

*eid-xor -bs g192 in_bs error_pattern out_bs*

where *in_bs* and *out_bs* are the input and output bitstreams both in the G.192 format [i.8] and *error_pattern* the error pattern in byte format.

Alternatively, a Python® version of this tool is also available and can be used in a similar way:

*eid-xor.py -bs g192 in_bs error_pattern out_bs*

#### 7.2.5.3 flipG192

This tool can flip a number of bits in a number of frames in a G.192 bitstream. It is provided as C source code and is used for the error protection test with a correctable number of flipped bits. It can be used as follows:

*flipG192 in_bs out_bs FLIPS FRAMES SEED VERBOSE*

where *in_bs* and *out_bs* are the input and output bitstreams both in the G.192 format, *FLIPS* is the number of bits to flip in every frame, *FRAMES* is the number of frames to flip in percent, *SEED* is an integer seed for the random generator and *VERBOSE* specifies if the information about the flipped bits and the respective frames shall be shown (1) or not (0).

#### 7.2.5.4 G.192 bitstream format

The test implementation shall be able to read and write a bitstream in the G.192 format [i.8]. All tests within this script use this format.

Each bit of the bitstream data is represented by a 16-bit word and is preceded by a synchronization word and the length word. A bit '0' is coded as the softbit '0x007F' and a bit '1' is coded as softbit '0x0081'. The synchronization word can take the following values:

- '0x6B21' representing a good frame
- '0x6B20' representing a bad/lost frame (bfi == 1)
- '0x6B22' representing a partially bad/lost frame (bfi == 2)

The length field contains the length (the total number of bits) as a 16-bit word.

#### 7.2.5.5 Note to platform-dependent conformance

To prepare the audio samples for the conformance test, it is recommended to use SoX (Sound eXchange) [i.9] for any operations on the audio samples in order to prepare them for the conformance test. SoX behaves differently on different platforms, meaning that the same resampling operation on the same file will not be bit-exact if executed on different platforms. Therefore, to avoid such issues, it is recommended to use the SoX Windows-executable (together with Wine [i.10] on non-Windows platforms) to avoid such issues.

#### 7.2.5.6 Reference conformance test script

The conformance test script is a Python® script that implements all test procedures mentioned within the present document. It can be used on an operating system with Python3 installed:

*lc3_conformance.py config.cfg [-v -w -keep]*

where *config.cfg* is the configuration file containing all operation points to be tested. Detailed instructions and the prerequisites for running this script are provided in the Readme.txt contained in archive ts_103634v010701p0.zip which accompanies the present document. An example configuration file is also provided within the *example_config.cfg* file.

#### 7.2.5.7 Bitstream Analyzer

This tool analyses the encoded bitstream and compares the original input with the decoded output to compute lossless metrics (clause 7.2.4a.1 and 7.2.4a.2). It can be used as follows:

*bitstream_analyzer.py in_wav out_wav bitstream nChannels* $f_s$ *bps*

where *in_wav* is the original input .wav file, *out_wav* is the decoded output .wav file, *bitstream* is the encoded bitstream file, *nChannels* is the number of audio channels, $f_s$ is the sampling rate in Hz, *bps* is the bit depth (16 or 24).

## 7.3 Conformance tests

### 7.3.1 Test groups

The LC3plus conformance tests are combined into the three groups:

- Core coder tests, see clause 7.3.2
- Concealment tests, see clause 7.3.3
- Channel coder tests, see clause 7.3.4

For the LC3plus high-resolution conformance, the tests above are modified and extended according to clause 7.3.5. For testing the dedicated LFE encoder operation mode, the test in clause 7.3.6 applies. For testing frame size 1,25 ms, the test in clause 7.3.7 applies. For the LC3plus lossless conformance, the tests are applied as in clause 7.3.8.

### 7.3.2 Core coder tests

#### 7.3.2.1 SQAM test

The SQAM Test aims to verify the intrinsic audio quality of an implementation under test. It uses the nine prepared test items (Table 7.1) to provide audio quality metrics in comparison to the reference implementation.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.2.2 Band limitation test

The band limitation test verifies the correct implementation of the bandwidth detector/limiter inside the LC3plus encoder and decoder. Therefore, the item *Female_Speech_German* from the EBU SQAM CD is resampled and low pass filtered to create the following test configurations.

**Table 7.2: Test Configurations for Band Limitation Test**

| Sampling Rate [kHz] | Bandwidth | Bitrate [bytes / frame] |
|---|---|---|
| 16 | NB | 40 |
| 24 | NB, WB | 60 |
| 32 | NB, WB, SSWB | 80 |
| 48 | NB, WB, SSWB, SWB | 115 |

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.2.3 Low pass test

The Low Pass Test shall verify the correct implementation of the cut-off frequency of 20 kHz used in the EuT. Therefore, the test is only relevant for sampling rates higher than 32 kHz. For this test, a signal consisting of white noise above 20 kHz is used. The energy $E$ of the output PCM file is calculated according to:

$$E = 10 \cdot log_{10} \sum_{n=1}^{N} tst_ref(n)^2 \tag{219}$$

$E$ should be below the limit of 70 dB, where $N$ is the total number of audio samples.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.2.4 Bitrate switching test

The conformance tool shall be used for verifying the rate switching capability of the codec at runtime. It is required for the test implementation to accept a switching file instead of the bitrate parameter. The test implementation shall detect such a switching file and initialize the codec to the first bitrate from the bit rate switching file. The bitrate switching test is carried out for all frame sizes with the respective bitrate switching files and is following the same test procedure as outlined in the SQAM tests (clause 7.3.2.1).

Switching files are generated as a list of 64 bit values, where each value indicates the bit rate for a single frame. The rate switching test generates one or more switching profiles and executes the SQAM test using the switching profiles instead of the bit rate. The switching file shall contain all possible bit rate steps from the minimum to the maximum supported bit rate.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.2.5 Bandwidth switching test

The conformance tool shall be used for verifying the bandwidth switching capability of the codec at runtime. It is required for the test implementation to accept a bandwidth switching file. The test implementation shall detect such a switching file.

Switching files are generated using the STL gen_rate_profile tool according to clause 7.2.5.1. The switching values are provided in Hz, i.e. 4 000 stands for NB audio bandwidth. The switching pattern shall contain all typical audio bandwidths supported by the sampling rate, e.g. for sampling rate 24 000, the switching file shall contain the values 4 000, 8 000 and 12 000.

The bandwidth switching test generates one or more switching profiles and executes the SQAM test using the switching profiles instead of the bit rate.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

## 7.3.3 Concealment tests

### 7.3.3.1 Packet loss concealment

The PLC tests shall verify the correct implementation of the packet loss concealment. Two PLC tests shall be carried out: a test with a 10 % random error pattern and a test with a 10 % burst error pattern. These tests follow the same procedure as the SQAM decoder test and add an additional error insertion step between encoding with the ER and decoding with the DR and the DuT:

- The eid-xor tool (clause 7.2.5.2) is used to add an error pattern to the bitstreams. The error pattern is provided within the files 'plc_fer_eid.dat' (10 % random pattern) and 'plc_bfer_eid.dat' (10 % burst pattern).
- Items are generated only for the decoder module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.3.2 Partial concealment

This test shall verify the correct implementation of the partial concealment.

This test follows the same procedure as the packet loss concealment test (clause 7.3.3.1) and all bitstreams are in addition encoded with the channel encoder in the highest error protection mode (4). The eid-xor tool (clause 7.2.5.2) is used to add a bit error pattern to the bitstreams. The error pattern is provided within the file 'pc_ber_3percent.dat'.

Items are generated only for the decoder module only according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

## 7.3.4 Channel coder

### 7.3.4.1 Channel coder test for correctable frames

This test verifies the correct implementation of the channel coder together with the LC3plus core codec excluding packet loss concealment. The tests execute the SQAM test, but protected bitstreams are created, bit errors are inserted using flipG192 (clause 7.2.5.3), distorted bit streams are decoded and the wave output files are compared by the quality metrics. The test includes all channel coder configuration outlined in Table 7.3.

**Table 7.3: Configuration of channel coder test**

| EP Mode | Number of flipped bits | Percent of frames to be flipped |
|---|---|---|
| 1 | 0 | 50 |
| 2 | 1 | 50 |
| 3 | 2 | 50 |
| 4 | 3 | 50 |

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

### 7.3.4.2 Channel decoder test for non-correctable frames

This test follows the procedure from the channel coder test for correctable frames (clause 7.3.4.1) but inserts a non-correctable amount of bit errors. Formula (220) is used to calculate the number of flipped bits and 50 percent of all frames are flipped:

$$flips = \frac{bitrate \cdot epmode \cdot frame_ms}{24\ 000} \tag{220}$$

where bitrate is the nominal bitrate in bit/s, epmode the error protection mode and frame_ms the frame size in ms.

The DR and the DuT use the corrupt bitstreams to decode them into audio wave files. The output audio files are afterwards compared according to clause 7.2.4.2. In this test, also the following channel decoder output variables are compared:

- bfi flag
- error report
- EPMR flag

The decoder under test shall be able to write out the output variables into separate binary files in an integer 64-bit format.

Items are generated only for the decoder module only according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

This test mandates that the respective decoder output variables are identical to the output of the reference decoder, i.e. that the binary files containing these variables are bit-exact.

#### 7.3.4.3 Error protection mode switching test

This test shall verify the correct update of all codec settings in case of error protection mode switching at runtime.

It is following the same test procedure as outlined in the SQAM tests (clause 7.3.2.1) and uses an error protection mode switching file as additional parameter.

The error protection mode switching file used for this test is provided within the package and contains the error protection mode value multiplied with a value of 100 in a 64-bit integer format for each frame. If the end of the file was reached while reading, the file is read again from the beginning. The LC3plus test implementation shall be able to read such a switching file and update all codec parameters accordingly.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

#### 7.3.4.4 Combined channel coding test for correctable frames

This test shall verify the correct behaviour of the combined channel coding for a stereo audio input. It follows the same test procedure as outlined in the channel encoder and decoder tests for correctable frames stated in clause 7.3.4.1.

The evaluation of the audio quality within these tests is done separately for each channel, i.e. the output stereo files are split into their individual channels before applying the quality metrics. The worst value out of all channels is then selected for further evaluation.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted. The comparison of the channel decoder output variables is applicable only for decoder tests and is not used for encoder and EncDec tests.

#### 7.3.4.5 Combined channel coding test for non-correctable frames

This test shall verify the correct behaviour of the combined channel coding for a stereo audio input. It follows the same test procedure as outlined in the channel encoder and decoder tests for non-correctable frames stated in clause 7.3.4.2. The evaluation of the audio quality is performed as outlined in clause 7.3.4.4.

Items are generated depending on the tested module according to clause 7.2.3. Quality metrics according to clause 7.4 are conducted.

#### 7.3.4.6 Void

## 7.3.5 High-resolution mode test

### 7.3.5.1 Core coder tests

For testing the high-resolution mode the following changes apply to the test procedures:

- SQAM test (clause 7.3.2.1):
  - ODG is measured with the floating-point reference executable as DR and ER.
  - ODG threshold shall be 0,02 for all bitrates ≥ the lowest recommended rate in Table 5.2. For bitrates below the lowest recommended rate in Table 5.2, the ODG threshold shall be determined according to equation (220.5) as for all other tests.
  - RMS threshold shall be k = 22, except when frame duration is 1,25 ms and a bitrate is used where LTPF is active, then k = 14.
  - $RMS_{max.\ abs.\ diff}$ threshold shall be 0,00001872, except when frame duration is 1,25 ms and a bitrate is used where LTPF is active, then the threshold is 0,00148.
- Bitrate switching test (clause 7.3.2.4):
  - ODG is measured with the floating-point reference executable as DR and ER.
  - ODG threshold shall be 0,02 for all bitrates ≥ the lowest recommended rate in Table 5.2. For bitrates below the lowest recommended rate in Table 5.2, the ODG threshold shall be determined according to equation (220.5) as for all other tests.
  - RMS threshold shall be k = 22.
  - $RMS_{max.\ abs.\ diff}$ threshold shall be 0,00001872.
- Low pass test (clause 7.3.2.3) is N/A.
- Band limitation test (clause 7.3.2.2) is N/A.
- Bandwidth switching test (clause 7.3.2.5) is N/A.

### 7.3.5.2 Concealment tests

Changes compared to clause 7.3.3:

- RMS or MLD is measured with the floating-point reference executable as DR and ER.
- RMS threshold shall be k = 22.
- $RMS_{max.\ abs.\ diff}$ threshold shall be 0,00001872.

### 7.3.5.3 Channel coder

Changes compared to clause 7.3.4:

- ODG, RMS or MLD is measured with the floating-point reference executable as DR and ER.
- ODG threshold shall be 0,02 for all bitrates ≥ the lowest recommended rate in Table 5.2. For bitrates below the lowest recommended rate in Table 5.2, the ODG threshold shall be determined according to equation (220.5) as for all other tests.
- RMS threshold shall be k = 22.
- $RMS_{max.\ abs.\ diff}$ threshold shall be 0,00001872.

For all channel coder tests, the effective net bitrate shall be used for the delta ODG threshold definition.

### 7.3.5.4 Precision tests

#### 7.3.5.4.1 General

The precision of an implementation under test, especially a fix-point implementation, shall be measured as outlined in the following:

The measurement is carried out on pure sinusoidal signals with an amplitude of -3 dB, a precision of at least 24 bits per audio sample and a duration of one second. The sinusoidal sequence $x_n$ is generated by:

$$x_n = \cos\left(\frac{2\,\pi\,f}{f_s}\cdot n\right)\ for\ n = 0..f_s - 1, \tag{220a}$$

where $f$ denotes the frequency of the sinusoid under test, and $f_s$ denotes the sampling rate and $n$ the time index.

These test sequences are subsequently encoded and decoded in high resolution mode. The coding should be conducted using the maximum bit rate for each frame duration. The decoded test file is here denoted as coded_output.wav.

The precision shall be measured for $n = 100$ frequency steps equally spaced in the logarithmic domain over the complete spectrum resulting in the frequencies:

$$\mathrm{f(i)} = 10^{i\frac{\log_{10}\left(\frac{f_S}{2}-1\right)}{n}} \quad \text{for i} = 1, 2, \ldots, \mathrm{n} \tag{220.1}$$

and additionally, 1 kHz frequency.

The test point at 1 kHz and the worst value over all frequencies shall be checked against the thresholds.

For measuring the encoder or decoder precision alone, the floating-point reference executable shall be used as counterpart.

#### 7.3.5.4.2 Total Harmonic Distortion plus Noise

The Total Harmonic Distortion plus Noise (THD+N) value is calculated by comparing the energy of the coded output to the energy of the sinusoidal sequence after applying a notch-filter to remove the sinusoidal component.
Let $s_n, n = 0..N-1$, denote the sequence of samples from coded_output.wav containing test signal frequency $f$.

The distortion on the signal is then calculated as:

$$y_n(f) = s_n - 2\cos\left(\frac{2\,\pi\,f}{f_s}\right)s_{n-1} + s_{n-2} + 1{,}9\cos\left(\frac{2\,\pi\,f}{f_s}\right)y_{n-1} - 0{,}9025\,y_{n-2} \tag{220.2}$$

for $n = 2..N-1$, where $y_0$ and $y_1$ are defined to be 0. The THD+N value is then calculated as:

$$\mathrm{THD + N(f)} = 10\log_{10}\left(\frac{\sum_{n=n_0}^{N-n_0-1} y_n^2(f)}{\sum_{n=n_0}^{N-n_0-1} s_n^2(f)}\right), \tag{220.3}$$

with $n_0 = \frac{f_S}{10}$.

#### 7.3.5.4.3 Signal to Noise Ratio

The Signal to Noise Ratio (SNR) is calculated by:

$$\mathrm{SNR}(f) = 10\log_{10}\left(\frac{\sum_{n=n_0}^{N-n_0-1} x_n^2(f)}{\sum_{n=n_0}^{N-n_0-1}\left(s_n(f) - x_n(f)\right)^2}\right), \tag{220.4}$$

with $n_0 = \frac{f_S}{10}$ and $s_n$ being the sequence of samples from coded_output.wav containing test signal frequency $f$.

## 7.3.6 Low Frequency Effects (LFE) test

The test of the Low Frequency Effects (LFE) mode verifies the correct configuration of bandwidth detector, LTPF, TNS and noise filling on LC3plus encoder side. Therefore, a sine sweep signal with frequencies from 10 Hz to 250 Hz is generated and the EuT is compared to the reference implementation using MLD as quality metric.

As the test only verifies the EuT, additional tests for DuT, concealment and channel coder are required at the corresponding bitrate.

## 7.3.7 1,25 ms mode test

The tests for the 1,25 ms mode are basically the same as outlined in clauses 7.3.2 to 7.3.4. However, differences in ltpf behaviour might be observed due to different pitch stability decisions (see clause 5.4.9.4) between floating and fixed point. To ensure reliable conformance testing, a dedicated sequence of audio frames for which the ltpf behaviour may be different is silenced, i.e. the samples are replaced with zeros. The configurations for which this is done are listed under 'LTPF BITSTREAM CONDITIONS' in the lc3plus conformance script. This feature is enabled by default and can be disabled by removing the conditions.

## 7.3.8 Lossless mode test

### 7.3.8.1 General

The LC3plus lossless mode operates with or without a bitrate constraint as follows:

- Without bitrate constraint: In this case, no bitrate parameter is provided to the encoder. The encoder automatically determines the maximum number of bytes required for fully lossless encoding of a frame. For the conformance script, this is indicated by setting the bitrate as '0' in the config files (clause 7.2.5.6).
- With bitrate constraint: A target bitrate is specified with the padding option enabled. Padding ensures that each encoded frame contains a constant number of bytes, determined by the target bitrate, by appending additional bytes after the encoded audio data.

For both operations, only the SQAM (clause 7.3.2.1) and packet loss concealment test (clause 7.3.3.1) are applicable. The following changes are applicable to the tests:

For generating the items (clause 7.2.1) with higher sampling rates (i.e. 96 kHz and 192 kHz), resampling is performed differently compared to other sampling rates. Instead of using SoX for resampling, polyphase resampling is performed using the *resample_poly* function in the *scipy.signal* Python® module with a Hamming window. The exact implementation is provided in the LC3plus Conformance Script (clause 7.2.5.6). For generating 24-bit test items, low-level noise at -100 dBFS is added to ensure that the least significant bits contain meaningful signal content for lossless compression testing.

In addition to the items listed in clause 7.2.1, White Noise and Sine Sweep items corresponding to each sampling rate and bit-depth are also generated for lossless tests.

For the SQAM test, lossless metrics, namely delta compression and delta percentage of lossless samples, are measured in addition to quality metrics. When a bitrate is specified, a padding check is additionally performed. This is an internal consistency check to verify that the sum of calculated payload bytes and padding bytes matches the expected encoded bytes as determined by the bitrate and frame size.

### 7.3.8.2 Stereo Tests

In lossless coding mode, each channel encodes a variable number of bytes per frame depending on the signal content, so the left and right channels may carry different payload sizes. Because the G.192 format provides a single per-frame length field (clause 7.2.5.4), a combined stereo stream cannot represent two independently variable-length channels.

The reference software therefore writes the two channels into separate G.192 files, identified by '_L' and '_R' suffixes (e.g. output_L.g192, output_R.g192). The codec's command-line interface is unchanged; the split is applied to the intermediate bitstream files only. The error patterns are also applied independently to each channel file.

When in CBR mode, any potentially leftover bit budget from lossless encoding of the left channel are carried over and added to the bit budget for encoding the right channel. This allows optimum distribution of the available stereo budget over the two channels.

## 7.4 Mapping conformance test, module and quality metric

### 7.4.1 Encoder

Table 7.4 describes the available tests for an LC3plus encoder and the applicable quality metric.

**Table 7.4: EuT tests and metrics**

| Test Name | Metric |
|---|---|
| SQAM | RMS or ODG |
| Band limitation | RMS or ODG |
| Low pass | Energy |
| Bitrate switching | RMS or ODG |
| Bandwidth switching | RMS or ODG |
| Channel coder correctable frame | RMS or ODG |
| Channel coder error protection mode switching | RMS or ODG |
| Combined channel coding correctable frame | RMS or ODG |
| Precision | THD+N and SNR |
| Low-frequency effects | MLD |

### 7.4.2 Decoder

Table 7.5 describes the available tests for an LC3plus decoder and the applicable quality metric.

**Table 7.5: DuT tests and metrics**

| Test Name | Metric |
|---|---|
| SQAM | RMS |
| Band limitation | RMS |
| Bitrate switching | RMS |
| Packet loss concealment | MLD or RMS |
| Partial concealment | MLD or RMS |
| Channel coder correctable frame | RMS |
| Channel Coder, Non-correctable frame | MLD or RMS |
| Channel coder error protection mode switching | RMS |
| Combined channel coding correctable frame | RMS |
| Combined channel coding non-correctable frame | MLD or RMS |
| Precision | THD+N and SNR |

### 7.4.3 Encoder-Decoder (EncDec)

Table 7.6 describes the available tests for an LC3plus EncDec and the applicable quality metric.

**Table 7.6: EuT-DuT tests and metrics**

| Test Name | Metric |
|---|---|
| SQAM | RMS or ODG |
| Band limitation | RMS or ODG |
| Low pass | Energy |
| Bitrate switching | RMS or ODG |
| Bandwidth switching | RMS or ODG |

## 7.5 Quality metric thresholds

The thresholds for each quality metric are outlined in Table 7.7. For each test, the conformance criteria stated in clause 7.6 apply.

**Table 7.7: Thresholds for quality metrics**

<table>
<tr><th rowspan="2">Metric</th><th colspan="3">Threshold</th></tr>
<tr><th colspan="2">High-Resolution Tests</th><th>All other Tests</th></tr>
<tr><td>RMS k</td><td colspan="2">k = 22</td><td>k = 14</td></tr>
<tr><td>RMS<sub>max. abs.diff</sub></td><td colspan="2">0,00001872</td><td>0,00148</td></tr>
<tr><td rowspan="2">ODG</td><td>Bitrates ≥ lowest recommended rate</td><td>bitrates < lowest recommended rate</td><td rowspan="2">0,06 | 0,08 | 0,12 | 0,15 (see note 1)</td></tr>
<tr><td>0,02</td><td>0,06 | 0,08 | 0,12 | 0,15 (see notes 1 and 2)</td></tr>
<tr><td>Energy</td><td colspan="3">70</td></tr>
<tr><td>MLD</td><td colspan="3">4</td></tr>
<tr><td>THD+N (1 kHz)</td><td colspan="3">-120 dB</td></tr>
<tr><td>worst THD+N over all frequencies</td><td colspan="3">-110 dB</td></tr>
<tr><td>SNR (1 kHz)</td><td colspan="3">120 dB</td></tr>
<tr><td>worst SNR over all frequencies</td><td colspan="3">110 dB</td></tr>
<tr><td>Binary file (channel coder debug data)</td><td colspan="3">Files shall be bit-exact</td></tr>
<tr><td colspan="4">NOTE 1: The delta threshold is set depending on the ODG of the reference file ($ODG_{ref}$) and the sampling frequency according to equation (220.5).<br>NOTE 2: The lowest recommended bitrates are found in Table 5.2.</td></tr>
</table>

$$delta_threshold(ODG_{ref}, f_s) = \begin{cases} 0{,}06 & for\ ODG_{ref} > -1 \ \ and\ f_s \neq 8kHz \\ 0{,}08 & for\ ODG_{ref} > -2{,}3\ and\ f_s \neq 8kHz \\ 0{,}12 & for\ ODG_{ref} \leq -2{,}3\ and\ f_s \neq 8kHz \\ 0{,}15 & for\ f_s = 8kHz \end{cases} \quad (220.5)$$

## 7.5a Lossless metric thresholds

The thresholds for each lossless metric are outlined in Table 7.7a. For each test, the conformance criteria stated in clause 7.6 apply.

**Table 7.7a: Thresholds for Lossless metrics**

| Metric | Threshold |
|---|---|
| Compression | 0,02 |
| Lossless Samples [%] | 0,5 |

## 7.6 Conformance criteria

An LC3plus implementation shall pass all required conformance tests to be considered as a conformant implementation. The required codec configurations and conformance test may depend on the application as described in clause 7.7.2. If not stated otherwise, all conformance tests listed in clause 7.7.1 shall be fulfilled.

A conformance test is considered as passed if all test permutations pass the threshold condition (clauses 7.5 and 7.5a) with the required quality metric or lossless metric. In case more than one quality metric or lossless metric is allowed, the conformance test shall pass all test permutations for one dedicated quality metric. Mixing the pass/fail results of different quality and lossless metrics shall not be allowed. Only one quality metric or lossless metric can be selected in the conformance reference script for each test. A conformance test can be considered as failed if at least one of the test conditions of a test permutation does not pass the threshold criteria.

# 7.7 Codec tests

## 7.7.1 General LC3plus test

LC3plus codec parameter configurations for testing are:

- All configurations listed in Tables 5.1 and 5.2
- Channel coder enabled/disabled
- Concealment enabled

For a full compliant implementation, the conformance criteria in clause 7.5 for all conformance tests listed in clause 7.4 shall be fulfilled using the given parameters above.

## 7.7.2 Applications

The conformance tests depend on the required application. Application test specifications may require additional tests. The application typically defines the codec configuration parameters (clause 7.2.2), i.e. bit rate, sampling rate, etc., and which conformance test groups are required for which modules (clause 7.2.3).

Table 7.8 gives an example which application may require particular conformance tests.

**Table 7.8: Example conformance tests for specific applications**

| LC3plus application | Codec configuration | | | Conformance tests group (see clause 7.3.1) (see note 1) | | |
|---|---|---|---|---|---|---|
| | Sampling rate [Hz] | Frame size [ms] | Bit rate [bytes per frame] | Core coder | Concealment | Channel Coder |
| **LC3plus WB VoIP** | 16 000 | 10 | 40 | Enc, Dec, EncDec | Dec | N/A |
| **LC3plus WB Voice DECT** | 16 000 | 10 | 40 | Enc, Dec, EncDec | Dec | Enc, Dec |
| **LC3plus music DECT** | 48 000 | 10 | 80, 120, 160 (see note 2) | Enc, Dec, EncDec | Dec | Enc, Dec |
| **LC3plus low delay DECT** | 32 000 | 2,5 | 40, 80 | Enc, Dec, EncDec | Dec | Enc, Dec (see note 3) |

NOTE 1: Some conformance tests are conducted for the modules encoder (enc), decoder (dec) and codec (EncDec) separately.
NOTE 2: As LC3plus operates in dual-mono for stereo signals, the conformance tests are applied on mono signals only.
NOTE 3: For some bit rates, the channel coder operates on combined stereo payloads (see clause 7.3.4.4).

# Annex A (normative): Application layer forward error correction

## A.1 Channel Coder

### A.1.1 Overview

The LC3plus channel coder features for every slot size from 40 to 400 bytes four different protection classes, also referred to as EP modes. Mode 1 provides strong error detection capability and modes 2 to 4 provide in addition increasingly strong error correction capability. The EP modes are switchable on the fly which enables the device to adapt to varying signal strengths. Furthermore, an Error Protection Mode Request (EPMR) is transmitted inside a protected LC3plus frame in order to request a protected LC3plus frame with a desired protection strength from the remote sender.

An example of the LC3plus codec and the channel coder operated by a control unit is displayed in Figure A.1.

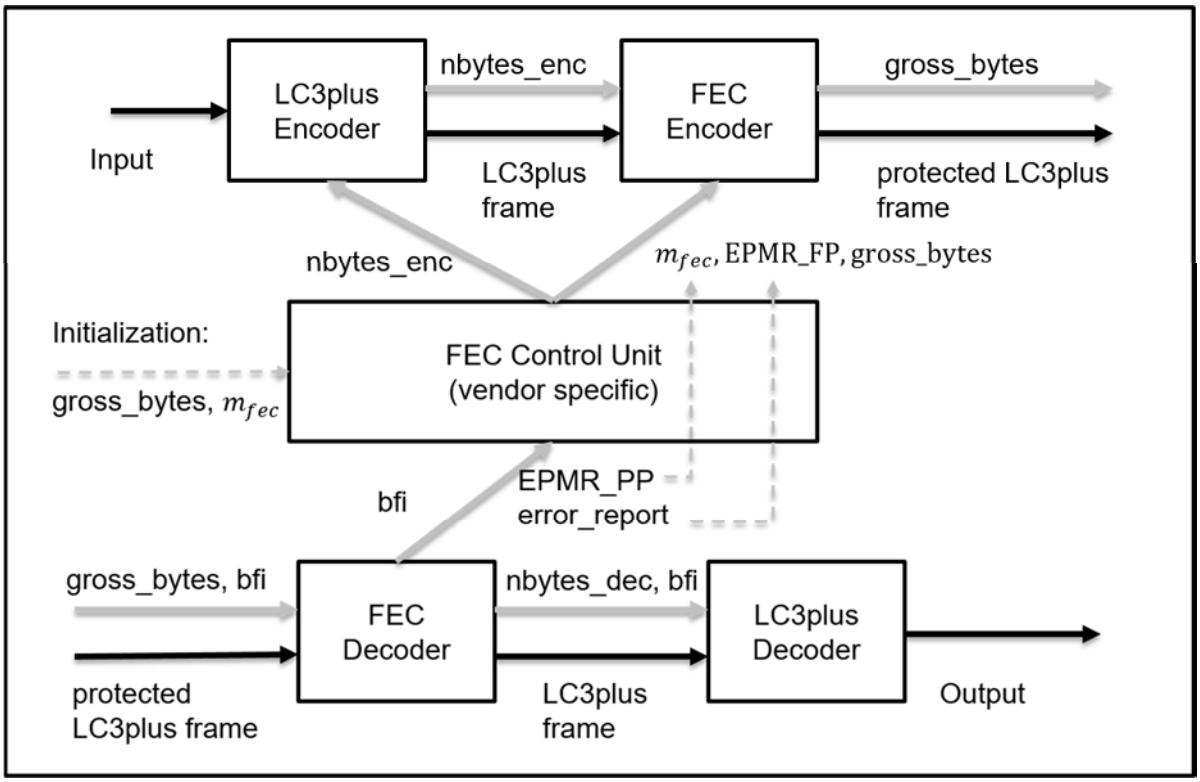

**Figure A.1: LC3plus Codec with Error Protection (FP perspective)**

The setup is identical in FP and PP but for simplicity the FP perspective is taken. At start-up, the FEC Control Unit is initialized with the target size gross_bytes which is the size of the protected LC3plus frame in bytes, and an initial EP mode. The FEC control unit then provides the LC3plus encoder with the target size for the current LC3plus frame, nbytes_enc, and the FEC Encoder with the EP mode $m_{fec}$ for the current frame and the EPMR of the fixed part EPMR_FP. The parameter EPMR_FP is added to the frame data to be sent to the PP inside the protected LC3plus frame. It should be noted that nbytes_enc is determined by the channel coder parameters $m_{fec}$ and gross_bytes. An example with gross_bytes equal to 40 (i.e. the case for DECT Normal Slots with GFSK) is given in Table A.1.

**Table A.1: Frame Sizes and Error Correction Capability for Normal Slots**

| EP mode: | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| nbytes: | 36 | 32 | 26 | 20 |
| error correction: | 0 bit errors | up to 3 bit errors | up to 9 bit errors | up to 18 bit errors |

For deciding on the current EP mode and EPMR_FP, the control unit can rely on information from the decoding chain. The FEC decoder takes as input the parameter gross_bytes and a protected LC3plus frame of that size. The FEC decoder performs mode detection (the EP mode not being transmitted explicitly), error detection and possibly error correction from which the value error_report is generated. E.g. if a protected frame is correctable, this value simply gives the number of corrected bits. It is a guidance to the control unit for selecting the FPs EPMR. The FEC decoder further retrieves the PPs EPMR which, in the simplest case, can be directly translated into an EP mode by the control unit. The FEC decoder furthermore generates a bad frame indicator bfi, the size of the encoder LC3plus frame nbytes_dec and the LC3plus frame itself which is provided to the LC3plus decoder.

An example for an FEC control unit is provided in Annex C.

The EPMR is protected by the channel coder and is therefore validated with very high confidence for correctable frames. In case of an uncorrectable frame, the EPMR may still be retrieved and often even validated with high or very high confidence. To differentiate these cases, the decoded EPMR (EPMR_PP in the present example) takes values from 0 to 11 whereas the encoded EPMR (EPMR_FP in the present example) takes values from 0 to 3, where the requested EP mode is EPMR + 1. If the decoded EPMR, $EPMR_{dec}$, falls into the range from 0 to 3 this indicated that its value directly corresponds to an EPMR and that it has been validated with very high accuracy (i.e. a confidence of roughly $1 - 2^{-16}$). This is in particular the case, when the received frame is correctable. If the decoded EPMR falls into the range from 4 to 7 this indicates that the EPMR has been validated with high accuracy (i.e. a confidence of roughly $1 - 2^{-8}$) and the corresponding EPMR is given by $EPMR_{dec} - 4$. Finally, if the decoded EPMR falls into the range from 8 to 11, this indicates that no validation of the EPMR value has been performed. In this case the corresponding EPMR is $EPMR_{dec}$ - 8 and its correctness depends on the integrity of the bit-location of 2 EPMR bits in the bitstream. These considerations should be taken into account when received EPMRs are evaluated by the FEC control unit.

For stereo content, the frames of left and right channel are channel encoded in a combined way as long as gross_bytes does not exceed 160. This is done to increase efficiency for low bit-rate stereo transmission. To this end, the two LC3plus frames are concatenated before channel encoding. If nbytes is larger than 160 the two frames are channel encoded separately and the two protected LC3plus frames are concatenated.

## A.1.2 Bitrate Conversion

The conversion from gross bitrate $gbr$ in bps to LC3plus codec $cbr$ bitrate is carried out as stated in the following for several frame durations.

For 10 ms frame duration, the gross bitrate is assumed to be a multiple of 800. The codec bitrate for the different EP modes is calculated as:

- EP mode 1

$$cbr = \mu_1(gbr) := gbr - 3\,200 \tag{A.1}$$

- EP mode 2

$$cbr = \mu_2(gbr) := gbr - 800\left(\left\lceil\frac{gbr}{6\,000}\right\rceil + 2 + \chi_{>32\,000}(gbr)\right), \tag{A.2}$$

where $\chi_{>A}(x)$ is defined to be 1 if $x > A$ and 0 otherwise.

- EP mode 3

$$cbr = \mu_3(gbr) := gbr - 800\left(2\left\lceil\frac{gbr}{6\,000}\right\rceil + 2 + \chi_{>32\,000}(gbr) + 2\chi_{>63\,200}(gbr)\right) \tag{A.3}$$

- EP mode 4

$$cbr = \mu_3(gbr) := gbr - 800\left(3\left\lceil\frac{gbr}{6\,000}\right\rceil + 2 + \chi_{>32\,000}(gbr) + 2\chi_{>63\,200}(gbr)\right) \quad (A.4)$$

$$void \quad (A.5)$$

For any frame duration except 7,5 ms, the codec bitrate in EP mode $m$ is calculated as:

$$cbr(N_{ms}) = \frac{10}{N_{ms}}\mu_m\left(gbr \cdot \frac{N_{ms}}{10}\right) \quad (A.6)$$

Table A.2 outlines typical channel coder rate and codec rate for a given $gbr$ for DECT applications.

**Table A.2: Codec rates for typical DECT configurations**

| $gbr$ $(DECT\ slot)$\ $EP\ mode$ | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 40 bytes, 10 ms interval | 36 bytes | 32 bytes | 26 bytes | 20 bytes |
| 80 bytes, 10 ms interval | 76 bytes | 66 bytes | 53 bytes | 42 bytes |

## A.1.3 General Channel Coder Parameters

### A.1.3.1 EP mode

The EP mode $m$ is a number from 1 to 4, where $m = 1$ provides only basic error protection and $m = 2, 3, 4$ provides increasing error correction capability. At the channel encoder the EP mode is denoted by $m_{fec}$ and at the channel decoder it is denoted $n_{fec}$.

### A.1.3.2 Slot Size

The slot size $N_s$ specifies the size of the channel encoded frame in octets and equals the parameter gross_bytes in Figure A.1. $N_s$ may take all integer values from 40 to 400, covering nominal bitrates from 32 to 320 kbit/s at a frame rate of 100 Hz.

### A.1.3.3 EPMR

The Error Protection Mode Request (EPMR) is a two-bit symbol represented by numbers from 0 to 3. The requested EP mode is EPMR + 1.

### A.1.3.4 Combined Channel Coding Flag

The combined channel coding flag $ccc_flag$ takes values 0 and 1 and indicates if the input data contains data from multiple audio channels.

## A.1.4 Derived Channel Coder Parameters

### A.1.4.1 Number of Code Words

The parameter $N_{cw}$ specifies the number of code words that are used to encode the data frame. It is derived from the slot size by:

$$N_{cw} := \left\lceil\frac{2N_s}{15}\right\rceil. \quad (A.7)$$

### A.1.4.2 Code Word Lengths

The parameter $L_i$ is defined for $i = 0 \ldots N_{cw} - 1$ and specifies the length of the $i$th code word in semi-octets. It is derived from the slot size $N_s$ as:

$$L_i := \left\lfloor \frac{2N_s - i - 1}{N_{cw}} \right\rfloor + 1. \quad (A.8)$$

### A.1.4.3 Hamming Distances

The parameter $d_{i,m}$ specifies the Hamming distance of the $i$th Code in EP mode $m$. It is given by:

$$d_{i,1} := \begin{cases} 1, & i = 0 \\ 0, & i > 0 \end{cases} \quad (A.9)$$

and for $m > 1$ by:

$$d_{i,m} := 2m - 1 \quad for\ i = 0 \ldots N_{cw} - 1. \quad (A.10)$$

### A.1.4.4 Number of Partial Concealment Code Words

The parameter $N_{pccw}$ specifies the number of partial concealment code words and is derived from slot size $N_s$ and EP mode $m$ by:

$$N_{pccw} := \begin{cases} \lfloor 0{,}080447761194030 \cdot N_s - 1{,}791044776119394 + 0{,}5 \rfloor, & m = 3\ and\ N_s \geq 80\ and\ ccc_flag = 0 \\ \lfloor 0{,}066492537313433 \cdot N_s - 1{,}970149253731338 + 0{,}5 \rfloor, & m = 4\ and\ N_s \geq 80\ and\ ccc_flag = 0 \\ 0, & else. \end{cases} \quad (A.11)$$

### A.1.4.5 Size of Partial Concealment Block

The parameter $N_{pc}$ specifies the size of the partial concealment block in semi-octets and is derived from slot size $N_s$ and EP mode $m$ by:

$$N_{pc} := \sum_{i=N_{cw}-N_{pccw}}^{N_{cw}-1} (L_i - d_{i,m} + 1). \quad (A.12)$$

### A.1.4.6 CRC Hash Sizes

The numbers $N_{CRC1}$ and $N_{CRC2}$, which correspond to sizes of CRC hash values, are derived from slot size and EP mode $m$ by:

$$N_{CRC1} := \begin{cases} 2, & m \geq 2\ and\ N_s = 40 \\ 3, & else \end{cases} \quad (A.13)$$

$N_{CRC2}$ is set to:

$$N_{CRC2} := \begin{cases} 2, & N_s \geq 80\ and\ m > 2\ and\ ccc_flag = 0, \\ 0, & else. \end{cases} \quad (A.14)$$

### A.1.4.7 Data Size

The parameter $N_p$ specifies the data size in a channel encoded frame of size $N_s$ encoded in EP mode $m$ in octets. Its value is given by:

$$N_p := N_s - N_{CRC1} - N_{CRC2} - \sum_{i=0}^{N_{cw}-1} \frac{d_{i,m} - 1}{2} \quad (A.15)$$

## A.1.5 Algorithmic Description of the Channel Encoder

### A.1.5.1 Input/Output

The channel encoder takes as input the slot size $N_s$, the EP mode $m_{fec}$, the Error Protection Mode Request $EPMR$, a data sequence $a_{dat}(0 \dots N_p - 1)$ of octets and a combined channel coding flag $ccc_flag$ and returns a sequence of octets $a_{cc}(0 \dots N_s - 1)$. Octets are interpreted as numbers from 0 to 255 according to the specified endianness.

### A.1.5.2 Data Pre-Processing

The data sequence is first split into a sequence $a_n(0 \dots 2N_p - 1)$ of semi-octets with reversed ordering, where $a_n(2k)$ holds the upper half of $a_{dat}(N_p - 1 - k)$ and $a_n(2k + 1)$ holds the lower half. In formulas this is:

$$a_n(2k) := \left\lfloor \frac{a_{dat}(N_p - 1 - k)}{16} \right\rfloor \tag{A.16}$$

and

$$a_n(2k + 1) := rem(a_{dat}(N_p - 1 - k), 16) \tag{A.17}$$

where $rem(x, y)$ denotes the remainder in the long division of $x$ by $y$, i.e. the uniquely determined number $r$, such that $0 \leq r < |y|$ and such that $x - r$ is divisible by $y$.

Next, CRC hash values are calculated on the bit-expansions of the sequences:

$$a_{n1}(0 \dots 2N_p - N_{pc} - 1) := a_n(0 \dots 2N_p - N_{pc} - 1) \tag{A.18}$$

and

$$a_{n2}(0 \dots N_{pc} - 1) := a_n(2N_p - N_{pc} \dots 2N_p - 1) \tag{A.19}$$

Note that $N_{pc}$ might be zero in which case $a_{n2}$ is the empty sequence. The bit-expansion of a semi-octet sequence $a(0 \dots N - 1)$is defined by the sequence $b(0 \dots 4N - 1)$, where:

$$b(4k + j) := bit_j(a(k))), \tag{A.20}$$

with $k$ ranging from 0 to $N - 1$ and $j$ ranging from 0 to 3 and where $bit_j$ is the function returning the $j$th bit according to the specified endianness.

The first CRC hash sequence, calculated on an extension of $a_{n1}$, has length $8N_{CRC1} - 2$ and the binary generator polynomials are given by:

$$p_{14}(x) = 1 + x^2 + x^6 + x^9 + x^{10} + x^{14} \tag{A.21}$$

and

$$p_{22}(x) = 1 + x^3 + x^5 + x^8 + x^9 + x^{10} + x^{11} + x^{16} + x^{19} + x^{22} \tag{A.22}$$

The second CRC hash sequence, calculated on $a_{n2}$, has length $8N_{CRC2}$ and the binary generator polynomial is given by:

$$p_{16}(x) = 1 + x + x^3 + x^5 + x^6 + x^7 + x^9 + x^{13} + x^{15} + x^{16} \tag{A.23}$$

The CRC hash sequence of length $k$ on a binary data sequence $b(0 \dots N - 1)$ for a given binary generator polynomial $p(x)$ of degree $k$ is defined as usual to be the binary sequence $r(0 \dots k - 1)$ such that the binary polynomial:

$$(x) = \sum_{i=0}^{k-1} r(i)\, x^i + \sum_{i=0}^{N-1} b(i)\, x^{i+k} \tag{A.24}$$

is divisible by $p(x)$.

Let $b_{n1}$ denote the bit-expansion of $a_{n1}$ and let $b_{n2}$ denote the bit-expansion of $a_{n2}$. Then the sequence $r_{n1}(0 \dots 8N_{CRC1} - 3)$ is set to be the hash sequence of length $8N_{CRC1} - 2$ calculated on the concatenated sequence:

$$b_{n1ext} = \left(bit_0(EPMR), bit_1(EPMR), b_{n1}(0) \dots b_{n1}\left(8N_p - 4N_{pc} - 1\right)\right). \quad (A.25)$$

Furthermore, $r_{n2}(0 \dots 8N_{CRC2} - 1)$ is set to be the second hash sequence of length $8N_{CRC2}$ calculated on $b_{n2}$. Note that $r_{n2}$ is the empty sequence if $N_{CRC2} = 0$.

The first pre-processed data sequence $b_{pp0}\left(0..8\left(N_p + N_{CRC1} + N_{CRC2}\right) - 1\right)$ is then defined by:

$$b_{pp0}(0 \dots 8N_{CRC1} - 3) := r_{n1}(0 \dots 8N_{CRC1} - 3), \quad (A.26)$$

$$b_{pp0}(8N_{CRC1} - 2) := bit_0(EPMR), \quad (A.27)$$

$$b_{pp0}(8N_{CRC1} - 1) := bit_1(EPMR) \quad (A.28)$$

$$b_{pp0}(8N_{CRC1} \dots 8(N_{CRC1} + N_{CRC2}) - 1) := r_{n2}(0 \dots 8N_{CRC2} - 1) \quad (A.29)$$

$$b_{pp0}\left(8(N_{CRC1} + N_{CRC2}) \dots 8\left(N_p + N_{CRC1} + N_{CRC2}\right) - 4N_{pc} - 1\right) := b_{n1}\left(0 \dots 8N_p - 4N_{pc} - 1\right) \quad (A.30)$$

and

$$b_{pp0}\left(8(N_{CRC1} + N_{CRC2} + N_P) - 4N_{pc} \dots 8\left(N_{CRC1} + N_{CRC2} + N_p\right) - 1\right) := b_{n2}\left(0 \dots 4N_{pc} - 1\right) \quad (A.31)$$

The final pre-processed data sequence is given by swapping the EPMR bits at positions $8N_{CRC1} - 2$ and $8N_{CRC1} - 1$ with bits at positions $k := 4\left(L_0 - d_{0,m_{fec}}\right)$ and $k + 1$, i.e.:

$$b_{pp}(N_{CRC1} - 2) := b_{pp0}(k) \quad (A.32)$$

$$b_{pp}(N_{CRC1} - 1) := b_{pp0}(k + 1) \quad (A.33)$$

$$b_{pp}(k) := b_{pp0}(N_{CRC1} - 2) \quad (A.34)$$

$$b_{pp}(k + 1) := b_{pp0}(N_{CRC1} - 1) \quad (A.35)$$

and

$$b_{pp}(n) := b_{pp0}(n) \quad (A.36)$$

for $n$ different from $8N_{CRC1} - 2$ , $8N_{CRC1} - 1$, $k$, and $k + 1$. Swapping of these bits ensures that the EPMR bits are stored in an EP mode independent bit positions.

The bit-sequence $b_{pp}$ is converted into a semi-octet sequence $a_{pp}\left(0 \dots 2\left(N_{CRC1} + N_{CRC2} + N_p\right)\right)$ by reversing the bit-expansion, i.e.:

$$a_{pp}(k) := b_{pp}(4k) + 2\, b_{pp}(4k + 1) + 4\, b_{pp}(4k + 2) + 8\, b_{pp}(4k + 3) \quad (A.37)$$

Note that it is not necessary to actually carry out the bit-expansions described in this clause as CRC hashes can be computed efficiently on data blocks.

## A.1.5.3 Reed-Solomon Encoding

For Reed-Solomon (RS) encoding the pre-processed data sequence $a_{pp}$ from clause A.1.5.2 is split into $N_{cw}$ sequences $D_i$, also referred to as data words, according to:

$$D_i\left(0 \dots L_i - d_{i,m_{fec}}\right) = a_{pp}\left(S_i \dots S_i + L_i - d_{i,m_{fec}}\right), \quad (A.38)$$

where $i$ ranges from 0 to $N_{cw} - 1$ and where the split points $S_i$ are inductively defined by $S_0 = 0$ and $S_{i+1} = S_i + L_i - d_{i,m_{fec}} + 1$.

The RS codes are constructed over $GF(16) = \frac{GF(2)}{x^4+x+1}$, where the residue class of $x$ in $\frac{GF(2)}{x^4+x+1}$ is chosen as unit group generator, denoted as usual by $\alpha$.

Semi-octets are mapped to elements of $GF(16)$ using the data-to-symbol mapping:

$$n \rightarrow [n] := bit_0(n)\,\alpha^0 + bit_1(n)\,\alpha^1 + bit_2(n)\,\alpha^2 + bit_3(n)\,\alpha^3. \tag{A.39}$$

The mapping is one-to-one and the inverse mapping is denoted $\beta \rightarrow \langle\beta\rangle$, such that $[\langle\beta\rangle] = \beta$.

With this notation the Reed-Solomon generator polynomials for Hamming distances 3, 5, and 7 are given by:

$$q_3(y) := [8] + [6]\,y + [1]\,y^2, \tag{A.40}$$

$$q_5(y) := [7] + [8]\,y + [12]\,y^2 + [13]\,y^3 + [1]\,y^4, \tag{A.41}$$

and

$$q_7(y) := [12] + [10]\,y + [12]\,y^2 + [3]\,y^3 + [9]\,y^4 + [7]\,y^5 + [1]\,y^6\,. \tag{A.42}$$

For $i$ ranging from 0 to $N_{cw} - 1$ the RS redundancy sequences $R_i\left(0 \ldots d_{i,m_{fec}} - 2\right)$ for the data words $D_i$ are calculated. These are the (uniquely determined) seqences of semi-octets such that the polynomial:

$$f(y) := \sum_{k=0}^{d_{i,m_{fec}}-2} [R_i(k)]\,y^k + \sum_{k=0}^{L_i - d_{i,m_{fec}}} [D_i(k)]\,y^{k+d_{i,m_{fec}}-1} \tag{A.43}$$

is divisible by $q_{d_{i,m_{fec}}}(y)$. The $i$th code word $C_i$ is then defined to be the sequence of $L_i$ semi-octets given by:

$$C_i\left(0 \ldots d_{i,m_{fec}} - 2\right) := R_i\left(0 \ldots d_{i,m_{fec}} - 2\right) \tag{A.44}$$

and

$$C_i\left(d_{i,m_{fec}} - 1 \ldots L_i - 1\right) := D_i\left(0 \ldots L_i - d_{i,m_{fec}}\right) \tag{A.45}$$

Note that if $d_{i,m_{fec}} = 1$ the RS redundancy sequence is empty and $C_i$ simply equals $D_i$.

## A.1.5.4 Mode Signalling

The EP mode $m_{fec}$ is not explicitly transmitted but rather signalled implicitly by coloring the first 6 code words by mode dependent coloration sequences, i.e.:

$$CC_i(k) := \begin{cases} bitxor(C_i(k), sig_{m_{fec}}(k)) & i < 6 \\ C_i(k) & else, \end{cases} \tag{A.46}$$

where $bitxor(a, b)$ denotes the bit-wise xor operation on two semi-octets. The signalling sequences $sig_m$ are given by:

$$sig_1(0..14) = (0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0) \tag{A.47}$$

$$sig_2(0..14) = (7, 15, 5, 6, 14, 9, 1, 3, 12, 10, 13, 3, 2, 0, 0) \tag{A.48}$$

$$sig_3(0..14) = (7, 11, 14, 1, 2, 3, 12, 11, 6, 15, 7, 6, 12, 0, 0) \tag{A.49}$$

$$sig_4(0..14) = (6, 15, 12, 2, 9, 15, 2, 8, 12, 3, 10, 5, 4, 0, 0) \tag{A.50}$$

Note that code word coloration leaves the EPMR bits located in $C_0(L_0 - 1)$ unchanged.

### A.1.5.5 Code Word Multiplexing

The sequences $CC_i$ are multiplexed into a sequence of octets first by interleaving the semi-octets in a reversed order according to:

$$a_{il}(2N_s - N_{cw}\,k - i - 1) := CC_i(k), \tag{A.51}$$

where $i$ ranges from 0 to $N_{cw} - 1$ and $k$ ranges from 0 to $L_i - 1$, and then by pairing consecutive semi-octets according to:

$$a_{cc}(k) := a_{il}(2k) + 16\,a_{il}(2k+1) \tag{A.52}$$

where $k$ ranges from 0 to $N_s - 1$.

## A.1.6 Algorithmic Description of the Channel Decoder

### A.1.6.1 Input/Output

The channel decoder takes as input the slot size $N_s$, a sequence $z_{cc}(0 \ldots N_s - 1)$ of octets, and a combined channel coding flag $ccc_flag$ and returns the data size $N_p$, a sequence of decoded octets $z_{dat}(0 \ldots N_p - 1)$, a bad frame indicator $bfi$ taking values 0, 1, and 2, a EPMR estimate $VKNI$ taking values from 0 to 11, a number $error_report$ taking values from $-1$ to 480 (indicating the number of corrected bits if $bfi = 0$), bit position indicators $be_bp_left$ and $be_bp_right$ for partial concealment, and a number $epok_{flags}$ taking values from 0 to 15. If the channel coder exits with $bfi$ equal to 1, the number $error_report$ shall be -1.

The values $N_p$ and $z_{dat}(0 \ldots N_p - 1)$ are only specified if $bfi \neq 1$, and the value of the bit position indicators $be_bp_left$ and $be_bp_right$ is only specified if $bfi = 2$.

### A.1.6.2 Code Word De-Multiplexing

From the slot size $N_s$ the derived parameters $N_{cw}$ and $L_i$ are calculated according to clauses A.1.4.1 and A.1.4.2. The input sequence $z_{cc}(0 \ldots N_s - 1)$ is then split into a sequence $z_{il}(0 \ldots 2N_s - 1)$ of semi-octets according to:

$$z_{il}(2k) := rem(z_{cc}(k), 16) \tag{A.53}$$

and

$$z_{il}(2k+1) := \left\lfloor \frac{z_{cc}(k)}{16} \right\rfloor \tag{A.54}$$

for $k = 0 \ldots N_s - 1$, and code words $XX_i$ are extracted according to the data arrangements of clause A.1.5.5, i.e.:

$$XX_i(k) := z_{il}(2N_s - k\,N_{cw} - i - 1), \tag{A.55}$$

where $i$ ranges from 0 to $N_{cw} - 1$ and $k$ ranges from 0 to $L_i - 1$.

### A.1.6.3 Mode Detection

#### A.1.6.3.1 Overview

Mode detection aims at recovering the EP mode $m_{fec}$ by analysing the code words $XX_i$, where $i$ ranges from 0 to 5. The detected mode is denoted $n_{fec}$ and takes values from 0 to 4, where 0 indicates that no mode has been detected. Once a mode has been detected all derived codec parameters such as the data size, hamming distances, number of partial concealment code words, etc. are defined according to this mode. The mode is chosen from a list of candidate modes, initially containing EP modes 1 to 4, which is then narrowed down step by step.

### A.1.6.3.2 Stage 1

Stage 1 tries to determine whether the frame was encoded in EP mode 1. To this end, the first two syndromes of code word 0 are calculated, where the $k$th syndrome of code word $XX_i$ is defined to be the $GF(16)$ symbol:

$$S_k^{(i)} := \sum_{n=0}^{L_i-1} [XX_i(n)]\, \alpha^{kn}\,. \tag{A.56}$$

Mode 1 is selected if the following two conditions are satisfied:

1) $S_1^{(0)} = [0]$ and $S_2^{(0)} = [0]$.

2) The data, extracted according to the frame arrangement of $m_{fec} = 1$, passes the first cyclic redundancy check as outlined in clause A.1.6.7 with $z_{pp}(0 \ldots 2N_s - 2) = \left(XX_0(2 \ldots Li - 1), XX_1, \ldots, XX_{N_{cw}-1}\right)$.

If these conditions are satisfied, $error_report$ and $bfi$ are set to 0 and the channel decoder outputs the data $z_{dat}(0 \ldots N_p - 1)$ as generated in clause A.1.6.7. Otherwise, mode detection enters stage 2 and mode 1 is removed from the candidate list.

### A.1.6.3.3 Stage 2

Stage 2 tries to determine whether the frame was encoded in EP modes 2, 3, or 4. To this end, syndromes $S_k^{(i)}$ are calculated for $i = 0 \ldots 5$ and $k = 1 \ldots 6$.

If for one $m \in \{2,3,4\}$ the conditions:

$$S_k^{(i)} + \sum_{n=0}^{13} [sig_m(n)]\, \alpha^{kn} = [0] \tag{A.57}$$

are satisfied for $i = 0 \ldots 5$ and $k = 1 \ldots d_{i,m} - 1$, that is all syndromes coloured according to mode $m$ vanish, then $n_{fec} := m$ is selected and the channel coder proceeds to clause A.1.6.6. Note that such an $m$ is necessarily unique so the modes may be tested in any order.

If no such $m$ can be found, then mode detection calculates the error locator polynomials $\Lambda_{i,m}(y)$ for $i = 0 \ldots 5$ and $m = 2 \ldots 4$. This is done according to clause A.1.6.5.2 with $t = \frac{(d_{i,m}-1)}{2}$, and:

$$\sigma_k = S_k^{(i)} + \sum_{n=0}^{13} [sig_m(n)]\, \alpha^{kn}, \tag{A.58}$$

the coloured syndromes according to mode $m$, for $k = 1 \ldots 2t$.

All modes $m$ for which $\Lambda_{i,m}(y) = [0]$ for at least one $i$ from 0 to 5 are excluded from further consideration.

For the remaining modes a risk value is computed. The risk value $rsk(m)$ for mode $m$ is based on the degrees of the error locator polynomials $\Lambda_{i,m}(y)$ and is computed as mantissa exponent pair:

$$(\mu_m, \epsilon_m) := \Big(\Big(\Big(\big((\mu_{0,m}, \epsilon_{0,m}) * (\mu_{1,m}, \epsilon_{1,m})\big) * (\mu_{2,m}, \epsilon_{2,m})\Big) * (\mu_{3,m}, \epsilon_{3,m})\Big) * (\mu_{4,m}, \epsilon_{4,m})\Big) * (\mu_{5,m}, \epsilon_{5,m}), \quad (A.59)$$

where the mantissa exponent pairs $(\mu_{i,m}, \epsilon_{i,m})$ are specified in Table A.3, and where the multiplication of two mantissa exponent pairs is defined as follows: Given two pairs $(\mu, \epsilon)$ and $(\mu', \epsilon')$, where $0 \leq \mu, \mu' < 2^{15}$, the product $(\mu, \epsilon) * (\mu', \epsilon')$ is defined to be the pair $(\mu'', \epsilon'')$ given by:

$$\mu'' := \begin{cases} \lfloor \mu\, \mu' 2^{-14} \rfloor, & \mu\, \mu' < 2^{29} \\ \lfloor \mu\, \mu' 2^{-15} \rfloor, & else \end{cases} \quad (A.60)$$

and

$$\epsilon'' := \begin{cases} \epsilon + \epsilon', & \mu\, \mu' < 2^{29} \\ \epsilon + \epsilon' + 1, & else. \end{cases} \quad (A.61)$$

Such a mantissa exponent pair $(\mu, \epsilon)$ corresponds to the number $\mu \cdot 2^{\epsilon - 14}$.

**Table A.3: Fundamental Risk Values**

| $m \setminus \delta := \mathbf{deg}(\Lambda_{i,m})$ | 0 | 1 | 2 | 3 |
|---|---|---|---|---|
| 1 (only for $i = 0$) | (16 384, -8) | (26 880, -1) | NA | NA |
| 2 | (16 384, -8) | (26 880, -1) | NA | NA |
| 3 | (16 384, -16) | (26 880, -9) | (20 475, -2) | NA |
| 4 | (16 384, -24) | (26 880, -17) | (20 475, -10) | (19 195, -4) |

All modes $m$ for which the corresponding risk value $rsk(m)$ lies above a slot size dependent threshold $risk_thresh$ are removed from the list of candidate modes. The risk threshold is defined to be:

$$risk_thresh := \begin{cases} 21\,990 \cdot 2^{-37}, & N_s = 40 \\ 25\,166 \cdot 2^{-24}, & N_s > 40. \end{cases} \quad (A.62)$$

The remaining modes with risk value smaller than or equal to $risk_thresh$ are enumerated as $m_j, j = 1 \ldots n$, such that for every $j = 1 \ldots n-1$ either $rsk(m_j) < rsk(m_{j+1})$, or $rsk(m_j) = rsk(m_{j+1})$ and $m_j < m_{j+1}$ holds.

Starting from mode $m_1$, the error positions $n_{m_j,i,k}$ in code words $XX_i$ are determined according to clause A.1.6.5.3 with $\Lambda(y) = \Lambda_{i,m_j}(y)$ for $i = 0 \ldots 5$. If calculation of error positions was successful for all code words then $n_{fec} = m_j$ is selected and the channel decoder proceeds to clause A.1.6.5. Otherwise, if error positions cannot be determined for one index, the same procedure is carried out for mode $m_{j+1}$ while $j < n$. Otherwise, $n_{fec}$ is set to 0 indicating that no mode has been detected.

In case no mode is detected, i.e. $n_{fec} = 0$, $error_report$ is set to $-1$ and EPMR detection is carried out according to clause A.1.6.4 with $M = \{1, 2, 3, 4\}$ before the channel decoder exits with $bfi = 1$.

## A.1.6.4 EPMR Estimation when Frame is not decodable

In case the frame is not decodable the EPMR is estimated by analysing the first code word $XX_0$ and the corresponding error locator polynomials $\Lambda_{0,m}$ for all modes $m \in M$, where $M$ is a given set of candidate modes.

First all modes are removed from $M$ for which either:

- the error locator polynomial $\Lambda_{0,m}$ is not valid; or
- the risk value exponent $\epsilon_{0,m}$ as specified in Table A.3 is larger than $-8$.

The set of remaining modes is denoted $M_1$.

If $M_1$ is empty the EPMR estimate $VKNI$ is set to:

$$VKNI = bit_0\big(XX_0(L_0 - 1)\big) + 2\, bit_1\big(XX_0(L_0 - 1)\big) + 8, \tag{A. 63}$$

where the summand 8 indicates that this value is not validated.

If $M_1$ is not empty then let $m$ denote the element of $M_1$ for which the risk value exponent $\epsilon_{0,m}$ is minimal (note that such a mode always exists since $\epsilon_{0,1}$ and $\epsilon_{0,2}$ cannot both have value $-8$ by design of the signalling sequences). Then, error correction is performed on $XX_0$ according to clause A.1.6.5 with $n_{fec} = m$ and the EPMR estimate is derived from the corrected code word $XX_0^c$ as either:

$$VKNI = bit_0\big(XX_0^c(L_0 - 1)\big) + 2\, bit_1\big(XX_0^c(L_0 - 1)\big) + 4 \tag{A. 64}$$

if $\epsilon_{0,m} > -16$, where the summand 4 indicates that the EPMR was validated with high confidence, or:

$$VKNI = bit_0\big(XX_0^c(L_0 - 1)\big) + 2\, bit_1\big(XX_0^c(L_0 - 1)\big) \tag{A. 65}$$

if $\epsilon_{0,m} \leq -16$ indicating that the EPMR value was validated with very high confidence.

## A.1.6.5 Error Correction

### A.1.6.5.1 Overview

Full error correction is carried out only upon successful mode detection. In this case the error positions for $n_{n_{fec},i,k}$ for the first 6 codewords were already computed in clause A.1.6.3.3. Error correction may also be carried out only for the first code word for EPMR recovery. In this case the following steps are only carried out for $i = 0$.

The code words $XX_i$ with $i \leq 5$ are corrected by calculating the error symbols $\varepsilon_{i,k}$ according to clause A.1.6.5.4 with:

$$d = \deg\left(\Lambda_{i,n_{fec}}\right) \tag{A. 66}$$

$$\sigma_k = S_k^{(i)} + \sum_{l=0}^{13} \left[sig_{n_{fec}}(l)\right] \alpha^{kl}, \tag{A. 67}$$

$S_k^{(i)}$ being defined as in clause A.1.6.3.3, and:

$$\nu_k = n_{n_{fec},i,k}. \tag{A. 68}$$

The corrected code words are then defined by:

$$XX_i^c(k) = \begin{cases} bitxor(XX_i(k), < \varepsilon_{i,l} >) & k = \nu_l \; for \; some \; l \\ XX_i(k) & else, \end{cases} \tag{A. 69}$$

where $<\cdot>$ is the inverse data-to-symbol mapping specified in clause A.1.5.3.

For the remaining code words with index $i > 5$ error correction is performed by carrying out the usual steps:

1) Syndromes are calculated according to:

$$\sigma_k = \sum_{l=0}^{L_i - 1} [XX_i(l)]\, \alpha^{kl} \tag{A. 70}$$

for $k = 1 \ldots 2t$ with $t := \frac{d_{i,n_{fec}} - 1}{2}$.

2) If all syndromes are zero, the code word is presumed error free, and thus the corrected code word $XX_i^c$ is set to $XX_i$.

3) Otherwise, the error locator polynomial $\Lambda(y)$ is calculated according to clause A.1.6.5.2.

4) Upon success (i.e. $\Lambda(y) \neq [0]$), error positions $\nu_k$, $k = 0 \ldots d_i - 1$ with $d_i := \deg(\Lambda(y))$, are calculated according to clause A.1.6.5.3.

5) Upon success, error symbols $\varepsilon_{i,k}$, $k = 0 \ldots d_i - 1$, are calculated according to clause A.1.6.5.4 and error correction is performed according to:

$$XX_i^c(k) = \begin{cases} bitxor\left(XX_i(k), \langle\varepsilon_{i,l}\rangle\right) & k = \nu_l \; for \; some \; l \\ XX_i(k) & else. \end{cases} \quad (A.71)$$

If error correction fails for an index $i < N_{cw} - N_{pccw}$, i.e. one of the steps 3, 4 or 5 failed, the bad frame indicator $bfi$ is set to 1, $error_report$ is calculated as specified below and channel decoding is terminated.

For indices $i \geq N_{cw} - N_{pccw}$ a sequence $T\left(N_{cw} - N_{pccw} \ldots N_{cw} - 1\right)$ is defined as follows. If error correction fails for an index $i \geq N_{cw} - N_{pccw}$ or if the risk value exponent $\epsilon_{i,m}$ as specified in Table A.3 is larger than $-16$ the value $T(i)$ is set to 0, indicating that the data in code word $XX_i$ is not reliable without further validation. If error correction fails for such an index $i$, the corrected code word $XX_i^c$ is nevertheless defined to be $XX_i$ but the first bad frame indicator $bfi_0$ is set to 2.

The value of $error_report$ is determined as follows. If error correction failed for an index $i < N_{cw} - N_{pccw}$ then let $i_1$ denote the smalles index for which it failed and set $I = \{0, \ldots, i_1 - 1\}$. Otherwise let $I$ denote the set of all indices $0 < i < N_{cw}$ for which error correction succeded. The value of $error_report$ is then calculated as:

$$\sum_{i \in I} \sum_{j=0}^{d_i} bit_0(\langle\varepsilon_{i,j}\rangle) + bit_1\left(\langle\varepsilon_{i,j}\rangle\right) + bit_2(\langle\varepsilon_{i,j}\rangle) + bit_3(\langle\varepsilon_{i,j}\rangle) \quad (A.72)$$

that is the total number of bits corrected in code words $XX_i$ with $i \in I$.

If $N_s = 40$ the number of bit correction is artificially reduced to increase error detection. If all code words have been corrected successfully the first bad frame indicator is set depending on a mode dependent error threshold $emax_m$ given by:

$$emax_m := \begin{cases} 3 & m = 1 \\ 9 & m = 2 \\ 18 & m = 3 \end{cases} \quad (A.73)$$

If $error_report \leq emax_{n_{fec}}$ the first bad frame indicator $bfi_0$ is set to 0 and otherwise it is set to 1.

The value $epok_flags$ is calculated as follows. If $bfi_0 \neq 0$ it is set to 0. Furthermore, if no errors were detected, it is set to 15. Otherwise, a flag $epok_i$ is calculated for $i = 1..4$. If $N_s \neq 40$ the value $epok_i$ is calculated as:

$$epok_m = \begin{cases} 1, & \max\left(deg\left(\Lambda_{j,n_{fec}}\right), j = 0..N_{cw} - 1\right) < m, \\ 0, & else. \end{cases} \quad (A.73.1)$$

If $N_s = 40$, the value also depends on $emax_m$ and $error_report$ and is calculated as:

$$epok_m = \begin{cases} 1, & \max\left(deg\left(\Lambda_{j,n_{fec}}\right), j = 0..N_{cw} - 1\right) < m \; and \; error_report \leq emax_m, \\ 0, & else. \end{cases} \quad (A.73.2)$$

The value $epok_m$ thus gives an estimate whether the current frame would have been correctable in mode $m$. The value $epok_flags$ is then calculated as:

$$epok_flags = epok_1 + 2\, epok_2 + 4\, epok_3 + 8\, epok_4. \quad (A.73.3)$$

### A.1.6.5.2 Calculation of Error Locator Polynomials

The error locator polynomial is calculated from a sequence $\sigma_k$, $k = 1 \ldots 2t$, of symbols in $GF(16)$, where $t$ is a number from 1 to 3.

If $\sigma_k = [0]$ for $k = 1 \ldots 2t$, the error locator polynomial $\Lambda(y)$ is set to IETF RFC 3264 [1].

Otherwise, the determinants of matrices $M_l$ are calculated for $l = 1 \ldots t$, where:

$$M_1 := (\sigma_1), \tag{A.74}$$

$$M_2 := \begin{pmatrix} \sigma_1 & \sigma_2 \\ \sigma_2 & \sigma_3 \end{pmatrix}, \tag{A.75}$$

$$M_3 := \begin{pmatrix} \sigma_1 & \sigma_2 & \sigma_3 \\ \sigma_2 & \sigma_3 & \sigma_4 \\ \sigma_3 & \sigma_4 & \sigma_5 \end{pmatrix} \tag{A.76}$$

and

$$\det(M_1) = \sigma_1, \tag{A.77}$$

$$\det(M_2) = \sigma_1\sigma_3 + \sigma_2^2, \tag{A.78}$$

$$\det(M_3) = \sigma_1\sigma_3\sigma_5 + \sigma_1\sigma_4^2 + \sigma_2^2\sigma_5 + \sigma_3^3. \tag{A.79}$$

If all determinants are [0] for $l = 1 \ldots t$ the error locator polynomial $\Lambda(y)$ is set to [0], which is a non-valid error locator polynomial in the sense of clause A.1.6.5.3.

Otherwise, take $\tau$ to be the largest index from 1 to t such that $\det(M_\tau) \neq 0$. Then the coefficients of the error locator polynomial are computed as:

$$\begin{pmatrix} \lambda_\tau \\ \vdots \\ \lambda_1 \end{pmatrix} := M_\tau^{-1} \begin{pmatrix} \sigma_{\tau+1} \\ \vdots \\ \sigma_{2\tau} \end{pmatrix} \tag{A.80}$$

where the inverse matrices are given by:

$$M_1^{-1} := (\sigma_1^{-1}), \tag{A.81}$$

$$M_2^{-1} := \det(M_2)^{-1} \begin{pmatrix} \sigma_3 & \sigma_2 \\ \sigma_2 & \sigma_1 \end{pmatrix}, \tag{A.82}$$

$$M_3^{-1} := \det(M_3)^{-1} \begin{pmatrix} \sigma_3\sigma_5 + \sigma_4^2 & \sigma_2\sigma_5 + \sigma_3\sigma_4 & \sigma_2\sigma_4 + \sigma_3^2 \\ \sigma_3\sigma_4 + \sigma_2\sigma_5 & \sigma_1\sigma_5 + \sigma_3^2 & \sigma_1\sigma_4 + \sigma_2\sigma_3 \\ \sigma_2\sigma_4 + \sigma_3^2 & \sigma_1\sigma_4 + \sigma_2\sigma_3 & \sigma_1\sigma_3 + \sigma_2^2 \end{pmatrix}. \tag{A.83}$$

If $\lambda_\tau = [0]$, the error locator polynomial is set to $[0]$.

Otherwise, if $\tau = t$, the error locator polynomial is set to:

$$\Lambda(y) := [1] + \lambda_1 y + \ldots + \lambda_t y^t \tag{A.84}$$

and if $\tau < t$ it is further tested whether:

$$\sum_{k=1}^{\tau} \sigma_{\tau+k+n} \lambda_{\tau-k+1} = \sigma_{2\tau+n+1} \tag{A.85}$$

holds for $n = 0..2(t-\tau) - 1$. If all these equalities hold, then the error locator polynomial is set to:

$$\Lambda(y) := [1] + \lambda_1 y + \ldots + \lambda_\tau y^\tau \tag{A.86}$$

Otherwise, it is set to [0].

### A.1.6.5.3 Calculation of Error Positions

Error positions are calculated from the error locator polynomial:

$$\Lambda(y) := [1] + \lambda_1 y + \ldots + \lambda_t y^d. \tag{A.87}$$

The error locator polynomial is said to be valid, if it admits a representation:

$$\Lambda(y) = \prod_{k=0}^{t-1}(y + \alpha^{-n_k}), \text{ where } 0 \leq n_k < L_i \text{ and } n_k \neq n_l \text{ for } k \neq l \tag{A.88}$$

in which case the error positions are given by $n_k$ for $k = 0 \ldots d-1$. Otherwise, the list of error positions is empty.

The values $n_k$ can be determined by testing $\Lambda(\alpha^{-n}) = 0$ for $n = 0 \ldots L_i - 1$. Alternatively, tabulation of error locations indexed by $\lambda_i$ is possible and might be considerably faster.

### A.1.6.5.4 Calculation of Error Symbols

Error symbols are calculated from syndromes $\sigma_1, \ldots, \sigma_d$ and error positions $\nu_0, \ldots, \nu_{d-1}$ by solving the linear system:

$$A_d(\nu_0, \ldots, \nu_{d-1}) \begin{pmatrix} \varepsilon_0 \\ \vdots \\ \varepsilon_{d-1} \end{pmatrix} = \begin{pmatrix} \sigma_1 \\ \vdots \\ \sigma_d \end{pmatrix} \tag{A.89}$$

over $GF(16)$, where $A_d(\nu_0, \ldots, \nu_{d-1})$ are the Vandermonde matrices:

$$A_1(\nu_0) := (\alpha^{\nu_0}) \tag{A.90}$$

$$A_2(\nu_0, \nu_1) := \begin{pmatrix} \alpha^{\nu_0} & \alpha^{\nu_1} \\ \alpha^{2\nu_0} & \alpha^{2\nu_1} \end{pmatrix}, \tag{A.91}$$

and

$$A_3(\nu_0, \nu_1, \nu_2) := \begin{pmatrix} \alpha^{\nu_0} & \alpha^{\nu_1} & \alpha^{\nu_2} \\ \alpha^{2\nu_0} & \alpha^{2\nu_1} & \alpha^{2\nu_2} \\ \alpha^{3\nu_0} & \alpha^{3\nu_1} & \alpha^{3\nu_2} \end{pmatrix}. \tag{A.92}$$

The matrix inverses are given by:

$$A_1^{-1}(\nu_0) = (\alpha^{-\nu_0}) \tag{A.93}$$

$$A_2^{-1}(\nu_0, \nu_1) = \det\big(A_2(\nu_0, \nu_1)\big)^{-1} \begin{pmatrix} \alpha^{2\nu_1} & \alpha^{\nu_1} \\ \alpha^{2\nu_0} & \alpha^{\nu_0} \end{pmatrix}, \tag{A.94}$$

and

$$A_3^{-1}(\nu_0, \nu_1, \nu_2) = \det(A_3(\nu_0, \nu_1, \nu_2))^{-1} \begin{pmatrix} \alpha^{2\nu_1+3\nu_2} + \alpha^{2\nu_2+3\nu_1} & \alpha^{\nu_1+3\nu_2} + \alpha^{\nu_2+3\nu_1} & \alpha^{\nu_1+2\nu_2} + \alpha^{\nu_2+2\nu_1} \\ \alpha^{2\nu_0+3\nu_2} + \alpha^{2\nu_2+3\nu_0} & \alpha^{\nu_0+3\nu_2} + \alpha^{\nu_2+3\nu_0} & \alpha^{\nu_0+2\nu_2} + \alpha^{\nu_2+2\nu_0} \\ \alpha^{2\nu_0+3\nu_1} + \alpha^{2\nu_1+3\nu_0} & \alpha^{\nu_0+3\nu_1} + \alpha^{\nu_1+3\nu_0} & \alpha^{\nu_0+2\nu_1} + \alpha^{\nu_1+2\nu_0} \end{pmatrix} \tag{A.95}$$

with:

$$\det(A_2(\nu_0, \nu_1)) = \alpha^{\nu_0+2\nu_1} + \alpha^{\nu_1+2\nu_0} \tag{A.96}$$

and

$$\det(A_3(\nu_0, \nu_1, \nu_2)) = \alpha^{\nu_0+2\nu_1+3\nu_2} + \alpha^{\nu_1+2\nu_2+3\nu_0} + \alpha^{\nu_2+2\nu_0+3\nu_1} + \alpha^{\nu_0+2\nu_2+3\nu_1} + \alpha^{\nu_1+2\nu_0+3\nu_2} + \alpha^{\nu_2+2\nu_1+3\nu_0}. \tag{A.97}$$

## A.1.6.6 De-Colouration and RS Decoding

De-coloration according to the detected EP mode $n_{fec}$ is done by applying the corresponding signalling sequence from clause A.1.5.4, giving rise to de-colourated code words:

$$X_i(k) := \begin{cases} bitxor\left(XX_i^c(k), sig_{n_{fec}}(k)\right) & i < 6, \\ XX_i^c(k) & else. \end{cases} \tag{A.98}$$

Then, redundancy decoding is applied according to mode $n_{fec}$ producing the data words:

$$W_i\left(0 \dots L_i - d_{i,n_{fec}}\right) := X_i\left(d_{i,n_{fec}} - 1 \dots L_i - 1\right) \quad (A.99)$$

which are combined into the data sequence $z_{pp}(0 \dots N_p - 1)$, with $N_p$ as specified in clause A.1.4.7 with $m = n_{fec}$, according to:

$$z_{pp}\left(S_i \dots S_i + L_i - d_{i,n_{fec}}\right) := W_i\left(0 \dots L_i - d_{i,n_{fec}}\right) \quad (A.100)$$

for $i = 0 \dots N_{cw} - 1$, where the split points $S_i$ are defined as in clause A.1.5.3. This yields a sequence of length $2(N_p + N_{CRC1} + N_{CRC2})$. After RS redundancy decoding the FEC decoder proceeds to clause A.1.6.7 Data Post-Processing.

## A.1.6.7 Data Post-Processing

Data post-processing consists of hash removal and validation, and EPMR extraction. The sequence $z_{pp}$ from clause A.1.6.7 is expanded into the corresponding bit sequence $y_{pp}$ from which the sequence $y_{pp0}$ is derived by reversing the bit swap from clause A.1.5.2, i.e. swapping bits at positions $8N_{CRC1} - 2$ and $k := 4\left(L_0 - d_{0,n_{fec}}\right)$ and bits at positions $8N_{CRC1} - 2$ and $k + 1$.

The sequence $y_{pp0}$ is then split into sequences $i_{n1}$, $i_{n2}$, $y_{n1ext}$, and $y_{n2}$, corresponding to sequences $r_{n1}$, $r_{n2}$, $b_{n1ext}$, and $b_{n2}$ from clause A.1.5.2, given by:

$$i_{n1}(0 \dots 8N_{CRC1} - 3) := y_{pp0}(0 \dots 8N_{CRC1} - 3), \quad (A.101)$$

$$i_{n2}(0 \dots 8N_{CRC2} - 1) := y_{pp0}(8N_{CRC1} \dots 8(N_{CRC1} + N_{CRC2}) - 1), \quad (A.102)$$

$$y_{n1ext}(0 \dots 1) := y_{pp0}(8N_{CRC1} - 3 \dots 8N_{CRC1} - 1), \quad (A.103)$$

$$y_{n1ext}(2 \dots 8N_p - 4N_{pc} + 1) := y_{pp0}(8(N_{CRC1} + N_{CRC2}) \dots 8(N_{CRC1} + N_{CRC2} + N_P) - 4N_{pc} - 1 \quad (A.104)$$

and

$$y_{n2}(0 \dots 4N_{pc} - 1) := y_{pp0}(8(N_{CRC1} + N_{CRC2} + N_P) - 4N_{pc} \dots 8(N_{CRC1} + N_{CRC2} + N_p) \quad (A.105)$$

The two Cyclic Redundancy Checks (CRC) are carried out on $y_{n1ext}$ and $y_{n2}$ by re-calculating the hash sequences specified in clause A.1.5.2.

If the calculated $8N_{CRC1} - 2$ bit redundancy sequence for $y_{n1ext}$ specified in clause A.1.5.2 does not match $i_{n1}$ the bad frame indicator $bfi$ is set to 1 and the EPMR is estimated according to clause A.1.6.4 with $M = \{n_{fec}\}$. Otherwise, the EPMR estimate is set to:

$$VKNI = y_{n1ext}(0) + 2\, y_{n1ext}(1). \quad (A.106)$$

If the first CRC is passed and if $bfi_0 \neq 2$, the second CRC is carried out calculating the $8N_{CRC2}$ hash sequence for $y_{n2}$ as specified in clause A.1.5.2. If the result does not match the sequence $i_{n2}$ the bad frame indicator $bfi$ is set to 2, indicating the loss of partial concealment data. If the first CRC is passed and $bfi_0 = 2$ then $bfi$ is set to 2 without carrying out the second CRC.

If both CRCs are passed, the bad frame indicator $bfi$ is set to 0, indicating that the decoded data is valid.

If $bfi$ = 2, the position indicators $be_bp_left$ and $be_bp_right$ representing the left and right border of the potentially corrupted bits in the partial concealment block are determined from the sequence $T(N_{cw} - N_{pccw} \dots N_{cw} - 1)$ from clause A.1.6.5 in the following way.

If one of the two following conditions is true, then $be_bp_left$ is set to 0 and $be_bp_right$ is set to $4N_{pc} - 1$.

1) $T(i) = 0$ for $N_{cw} - N_{pccw} \leq i < N_{cw}$ (no trusted code words exist)

2) $T(i) = 1$ for $N_{cw} - N_{pccw} \leq i < N_{cw}$ (all code words are trusted but errors have been detected)

Otherwise, the position indicators are calculated as follows. If $T(N_{cw}-1)=0$, then $be_bp_left$ is set to 0. Otherwise, there exists a maximal index $i_0$ such that $T(i)=1$ for $i_0 \le i < N_{cw}$ and $be_bp_left$is calculated as:

$$be_bp_left = 4 \sum_{i=i_0}^{N_{cw}-1} \left(L_i - d_{i,n_{fec}} + 1\right). \tag{A.107}$$

Analogously, there exists a minimal index $i_1$ such that $N_{cw} - N_{pccw} \le i_1 < N_{cw}$ and $T(i_1)=0$, and $be_bp_right$ is calculated as:

$$be_bp_right = 4 \sum_{i=i_1}^{N_{cw}-1} \left(L_i - d_{i,n_{fec}} + 1\right) - 1\,. \tag{A.108}$$

If $bfi \neq 1$ the output data $z_{dat}$ is generated by reversing the pre-processing steps from clause A.1.5.2 by setting:

$$y_{n1}\left(0 \ldots 8N_p - 4N_{pc} - 1\right) := y_{n1ext}\left(2 \ldots 8N_p - 4N_{pc} + 1\right), \tag{A.109}$$

$$z_{n1}(k) = y_{n1}(4k) + 2\,y_{n1}(4k+1) + 4\,y_{n1}(4k+2) + 8\,y_{n1}(4k+2) \tag{A.110}$$

for $k = 0 \ldots 2N_p - N_{pc} - 1$,

$$z_{n2}(k) = y_{n2}(4k) + 2\,y_{n2}(4k+1) + 4\,y_{n2}(4k+2) + 8\,y_{n2}(4k+2) \tag{A.111}$$

for $k = 0 \ldots N_{pc} - 1$,

$$z_n\left(0 \ldots 2N_p - N_{pc} - 1\right) := z_{n1} \tag{A.112}$$

$$z_n\left(2N_p - N_{pc} \ldots 2N_p - 1\right) := z_{n2} \tag{A.113}$$

and

$$z_{dat}(k) := z_n\left(2N_p - 2k - 1\right) + 16\,z_n\left(2N_p - 2k - 2\right) \tag{A.114}$$

for $k = 0 \ldots N_p - 1$.

## A.1.7 Padding bytes

Padding bytes can be detected as the special decoder mode PADDING described in clause 5.4.2.4. The difference for operating with enabled channel coder is that the padding signalling elements (see Table 5.20) are read from the right side of the LC3plus frame. The additional number of bytes to be skipped as described in the padding length bits are located at the left side of the LC3plus frame in order to optimize the bitstream layout for partial concealment described in clause A.1.8.3.

The decoding procedure complies of a regular channel decoding step. Then when all potential PADDING signal 16-bit code words are detected, the number of padding signals is counted as *nsig_pad* and the number of padded bytes in the code words is counted as *nbytes_padd*. The left sided and right sided padding bytes are to be removed and the codec parameters need to be updated according to the real bit rate, see clause 5.7.

If padding is detected the output parameters of the LC3plus channel coder are updated according to the following pseudo code:

```
Np = Np – 2*nsig_pad – nbytes_pad;
Npc = max(Npc – 2*nbytes_sig, 0);
if (bfi == 2)
{
    if (be_bp_right < 8*nbytes_pad)
    {
        bfi = 0;
    }
    else
    {
        be_bp_left = max(be_bp_left – 8*nbytes_pad, 0);
        be_bp_right = be_bp_right – 8*nbytes_pad;
    }
}
```

If padding removal results in a payload size smaller than 20 bytes, i.e. the minimal LC3plus payload size, the bad frame indicator is set to 1.

# A.1.8 Bit error Concealment

## A.1.8.1 Reorder Bitstream

Before the channel coder is applied at encoder side, the bitstream is reordered such that preferably the coding data corresponding to the highest spectral coefficients including the residual signal are in front of the bitstream. At decoder side, the bitstream is read in a different way to repeal the reordering mechanism.

At encoder side, the bitstream bs is rearranged as follows:

$$\text{bs_rearranged(k)} = \begin{cases} \text{bs_enc(b_left} + k), & 0 \le k < \text{block_size} \\ \text{bs_enc}(k - \text{block_size}), & \text{block_size} \le k < \text{b_left} + \text{block_size} \\ \text{bs_enc}(k), & \text{b_left} + \text{block_size} \le \text{k} < \text{len} \end{cases} \quad (A.115)$$

where

$$\text{len} = 8 \cdot nbytes \quad (A.116)$$

and

$$\text{block_size} = 8\left\lfloor \frac{N_{pc}}{2} \right\rfloor \quad (A.117)$$

and $N_{pc}$ calculated in clause A.1.4.5 subject to the changes in clause A.1.7 and b_left is the byte position at the left side where the last block_size bits fit exactly in the bitstream, this means that the partial concealment block is [b_left:b_left+block_size-1].

The rearrangement of the bitstream $\text{bs}_{\text{rearranged}}$ at decoder side is done by initializing the arithmetic decoder byte position bp = block_size instead of 0 as done in clause 5.4.2.2. The border b_left at decoder side is determined as:

$$b_left = bp_side \quad , if\ bp{+}{+} == bp_side\ or\ bp == bp_side{-}{-}. \quad (A.118)$$

If bp++ == b_left, then bp = 0; if bp_side-- == b_left -1, then bp_side = (block_size/8)-1.

If the arithmetic decoder triggers an unexpected bit error in the partial concealment block, meaning outside the range $[be_bp_left: be_bp_right]$, then the lowest MDCT bin which cannot be decoded, $k_{be}$, is set to the highest frequency, which can be decoded outside the partial concealment block.

## A.1.8.2 Bit error Concealment trigger

If only part of the residual is missing, for example $be_bp_left$ and $be_bp_right$ only affect residual bits, then the bfi flag is set to zero and the residual block is skipped, before decoding the frame as a regular frame.

If $k_{be}$ is the lowest MDCT bin which cannot be decoded and $k_{be} < 4N_{ms}$, then the decoder shall apply packet loss concealment for the following five events:

a) if there are uncorrectable bit errors in the bitstream, except the partial concealment code block;

b) if the stability factor $\theta$ according to equation (157) is lower than 0,5;

c) if $\theta \ge 0{,}5$ and pitch_present $= 1$ as described in clause 5.4.2.3 and $k_{be} < \left\lceil 800 \frac{N_F}{f_s} \right\rceil$;

d) if $\theta \ge 0{,}5$ and pitch_present $= 1$ and $k_{be} <$ peak_detector$\left(\hat{X}_{prev}, N_F\right)$, where $\hat{X}_{prev}$ is the shaped spectrum of the last non-PLC frame; and

```
function [k_peak] = pc_peak_detector(X̂_prev, N_F)
block_size = 3;
thresh1 = 8;
```

```
fac = 0.3;

mean_block_nrg = mean(X̂_prev.^2);
maxPeak = 0;
k_peak = 0;

if abs(X̂_prev(0)) > abs(X̂_prev(1))
    block_cent = sum(X̂_prev(0:1).^2);
    if block_cent/block_size > thresh1*mean_block_nrg
        cur_max = max(abs(X̂_prev(0:1)));
        next_max = max(abs(X̂_prev(2:2+block_size-1)));

        if cur_max > next_max
            maxPeak = block_cent;
            k_peak = 1;

for k = 0:block_size-1
    if abs(X̂_prev(k+1)) >= abs(X̂_prev(k)) && abs(X̂_prev(k+1)) >= abs(X̂_prev(k+2))
        block_cent = sum(X̂_prev(k:k+block_size-1).^2);

        if block_cent/block_size > thresh1*mean_block_nrg
            cur_max = max(abs(X̂_prev(k:k+block_size-1)));
            prev_max = 0;
            for j = k-block_size:k-1
                if j > 0
                    prev_max = max(abs(X̂_prev(j)), prev_max);
            next_max = max(abs(X̂_prev(k+block_size:k+2*block_size-1)));

            if cur_max >= prev_max && cur_max > next_max
                if block_cent > fac*maxPeak
                    k_peak = k+block_size-1;
                    if block_cent >= maxPeak
                        maxPeak = block_cent;

for k = block_size.. N_F-(2*block_size)
    if abs(X̂_prev(k+1)) >= abs(X̂_prev(k)) && abs(X̂_prev(k+1)) >= abs(X̂_prev(k+2))
        block_cent = sum(X̂_prev(k:k+block_size-1).^2);

        if block_cent/block_size > thresh1*mean_block_nrg
            cur_max = max(abs(X̂_prev(k:k+block_size-1)));
            prev_max = max(abs(X̂_prev(k-block_size:k-1)));
            next_max = max(abs(X̂_prev(k+block_size:k+2*block_size-1)));

            if cur_max >= prev_max && cur_max > next_max
                if block_cent > fac*maxPeak
                    k_peak = k+block_size-1;
                    if block_cent >= maxPeak
                        maxPeak = block_cent;
```

e) if $\theta \geq 0{,}5$ and pitch_present $= 0$; and

$$\sum_{k=0}^{k_{be}-1} \widehat{X_{q,lG}}(k)^2 < 0{,}3 \sum_{k=0}^{N_F-1} \widehat{X_{q,lG}}(k)^2 \qquad \text{(A. 119)}$$

where $\widehat{X_{q,lG}}(k)$ is the quantized spectrum of the last non-PLC frame of clause 5.4.2.8.

If none of the five events triggers or $k_{be} \geq 4N_{ms}$, partial concealment of clause A.1.8.3 shall be applied.

## A.1.8.3 Partial Concealment

The partial concealment is a method to conceal the missing spectral lines, which for example are not available due to non-correctable bit errors in the partial concealment code block encapsulated by $be_bp_left$ and $be_bp_right$ as described in clause A.1.6.7, while decoding the rest of the payload as usual. Figure A.2 gives a decoder overview including the partial concealment processing blocks marked in green and the update steps marked in red which have to be done in every frame expect for frames which are concealed with PLC.

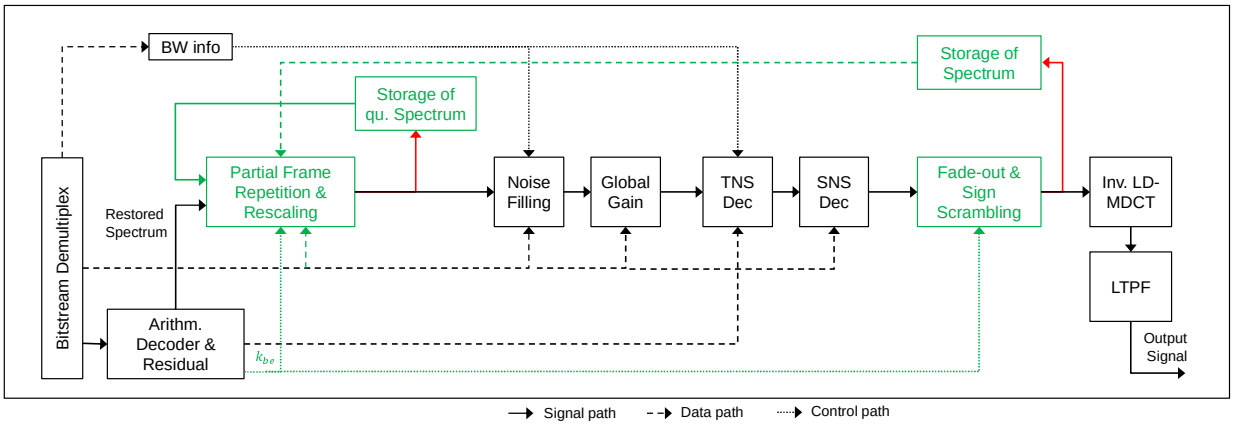

**Figure A.2: Decoder overview including partial concealment**

As the quantized spectrum $\widehat{X_q}$ is only valid from $0 \ldots k_{be} - 1$, the upper bins are synthesized as follows:

```
for k=k_be .. N_F − 1
  seed = (16831 + seed*12821) & 0xFFFF;
  if (seed < 0 && pitch_present == 0) || seed < randThreshold
    X̂_q(k) = −X̂_q,lG(k) · fac;
  else
    X̂_q(k) = X̂_q,lG(k) · fac;
  if |X̂_q(k)| < 0.625
    X̂_q(k) = 0;
```

with the initial value of seed = 24 607, $\text{pitch}_{\text{present}}$ from clause 5.4.2.3, $\widehat{X_q}(k)$ being the quantized spectrum of the current frame, $\widehat{X_{q,lG}}(k)$ being the quantized spectrum of the last non-PLC frame of clause 5.4.2.8, randThreshold being calculated as done in clause 5.6.3.2 and $fac$ being the rescaling factor:

$$fac = fac_{gg} \cdot fac_{ener} \tag{A.120}$$

where $fac$ is bounded by $0 \leq fac \leq 1$, and

$$fac_{gg} = \frac{gg_{prev}}{gg} \tag{A.121}$$

where $gg_{prev}$ is the global gain of the previous frame and $gg$ is the global gain of the current frame of clause 5.4.5 and if the following two conditions are met:

$$\begin{gathered} \frac{1}{k_{be}} \sum_{k=0}^{k_{be}-1} \hat{X}_{prev}(k)^2 > \frac{1}{N_F - k_{be}} \sum_{k=k_{be}}^{N_F-1} \hat{X}_{prev}(k)^2 \\ gg_{prev}^2 \cdot \sum_{k=0}^{k_{be}-1} \widehat{X_{q,lG}}(k)^2 > gg^2 \cdot \sum_{k=0}^{k_{be}-1} \widehat{X_q}(k)^2 \end{gathered} \tag{A.122}$$

then:

$$fac_{ener} = \sqrt{\frac{gg^2 \cdot \sum_{k=0}^{k_{be}-1} \widehat{X_q}(k)^2}{gg_{prev}{}^2 \cdot \sum_{k=0}^{k_{be}-1} \widehat{X_{q,lG}}(k)^2}}. \tag{A.123}$$

otherwise $fac_{ener} = 1$.

Afterwards, the residual decoding in clause 5.4.3 is skipped. Other than that, the frame is processed and handled as a regular good frame, meaning that the blocks noise filling, global gain, temporal noise shaping and spectral noise shaping are applied to form the intermediate spectrum $\hat{X}'(k)$ right before the IMDCT, see Figure A.2. To form the reconstructed spectrum $\hat{X}(k)$, the intermediate spectrum $\hat{X}'(k)$ is damped adaptively based on the two damping factors:

$$slow_k = \begin{cases} \sqrt[4]{0{,}8 + 0{,}2 \cdot \theta}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{0{,}8 + 0{,}2 \cdot \theta}, & for\ N_{ms} = 5 \\ 0{,}8 + 0{,}2 \cdot \theta, & otherwise \end{cases} \quad (A.124)$$

and

$$fast_k = \begin{cases} \sqrt[4]{0{,}3 + 0{,}2 \cdot \theta}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{0{,}3 + 0{,}2 \cdot \theta}, & for\ N_{ms} = 5 \\ 0{,}3 + 0{,}2 \cdot \theta, & otherwise \end{cases} \quad (A.125)$$

where $\theta$ is the stability factor according to equation (157), but between $scfQ_{-1}(k)$ and $scfQ(k)$. The corresponding cumulative attenuation factors $\text{cum_fading_slow_pc}_\text{k}$ and $\text{cum_fading_fast_pc}_\text{k}$ are derived as follows:

$$\text{cum_fading_slow_pc}_\text{k} = \text{cum_fading_slow_pc}_{\text{k}-1} \cdot \text{slow}_\text{k} \quad (A.126)$$

and

$$\text{cum_fading_fast_pc}_\text{k} = \text{cum_fading_fast_pc}_{\text{k}-1} \cdot \text{fast}_\text{k} \quad (A.127)$$

where $\text{cum_fading_slow_pc}_{\text{k}-1}$ and $\text{cum_fading_fast_pc}_{\text{k}-1}$ are the cumulative attenuation factors of the previous frame or 1 if nbLostFrames = 1, where nbLostFrames is the number of consecutive frames which are concealed with partial concealment plus the number of consecutive frames which are concealed with packet loss concealment right before partial concealment is used.

If the previous frame was concealed with packet loss concealment, the cumulative attenuation factors $\text{cum_fading_slow_pc}_{\text{k}-1}$ and $\text{cum_fading_fast_pc}_{\text{k}-1}$ are calculated as follows:

$$\text{cum_fading_slow_pc}_{\text{k}-1} = \begin{cases} \sqrt[4]{(0{,}8 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{(0{,}8 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}}, & for\ N_{ms} = 5 \\ (0{,}8 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}, & otherwise \end{cases} \quad (A.127.1)$$

and

$$\text{cum_fading_fast_pc}_{\text{k}-1} = \begin{cases} \sqrt[4]{(0{,}3 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}}, & for\ N_{ms} = 2{,}5 \\ \sqrt[2]{(0{,}3 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}}, & for\ N_{ms} = 5 \\ (0{,}3 + 0{,}2 \cdot \theta_{PLC})^{nrPlc}, & otherwise \end{cases} \quad (A.127.2)$$

where $\theta_{PLC}$ is the stability factor used in the previous packet loss concealment frame and $nrPlc$ is the number of consecutive frames concealed with packet loss concealment before the first partial concealment frame.

Finally, the damping is processed as follows:

```
ad_ThreshFac_start = 10;
ad_ThreshFac_end   = 1.2;
ad_threshFac = (ad_ThreshFac_start - ad_ThreshFac_end) * linFuncStartStop + ad_ThreshFac_end;
frame_energy = mean(X̂′(k)(k_be.. N_F − 1).^2);
energThreshold = ad_threshFac * frame_energy;
for k=k_be.. N_F − 1
    if (X̂′(k)^2) < energThreshold
        m = cum_fading_slow_pc;
        n = 0;
    else
        m = cum_fading_fast_pc;
        n = (cum_fading_slow_pc-cum_fading_fast_pc) * sqrt(energThreshold) * sign(X̂′(k));
    end
```

```
    X̂(k) = m * X̂'(k) + n;
end
```

to form the spectrum $\hat{X}(k)$ for clause 5.4.8.

# A.2 Redundancy frames

## A.2.1 Overview

A packet-based application layer forward error correction algorithm can be implemented with LC3plus as well. In [i.6], this mechanism is described as media specific FEC. This means a packet contains a primary encoded LC3plus frame and a secondary LC3plus frame which is delayed in time by an offset of t packets.

As packet loss usually coincides with high jitter, a jitter buffer manager can compensate for the high jitter and may forward the secondary LC3plus frame in order to compensate the missing primary frame. Primary and secondary frame might be identical in terms of configuration and bitrate or the secondary frame might be of lower bit rate and lower quality.

In the case that secondary LC3plus frames contain a lower audio bandwidth, the frames shall be labelled as secondary frames in the RTP frame type description. This flag shall be forwarded to the decoder. For LC3plus frames labelled as secondary frames, the decoder shall select the concealment strategy as done in clause A.1.8.2, which is the partial concealment algorithm described in clause A.1.8.3 or the frame loss concealment algorithm as described in clause 5.6.3, where $k_{be}$ is set to the lower bandwidth in the coded secondary frame.

If the partial concealment algorithm is selected, the same processing is done as described in clause A.1.8.3. The only difference is in the noise filling processing after partial concealment. If the bandwidth index $P_{bw}$ (see clause 5.4.2.3) from the previous frame is not the same as for the secondary frame, and the secondary frame contains a lower audio bandwidth than the primary frame, then the bandwidth index from the previous frame is used together with the noise filling gain $\widehat{L_{NF}}$ given in clause 5.4.4 of the previous frame for the MDCT bins beginning at $k_{be}$. However, this noise filling gain is further multiplied with $fac_{ener}$ as calculated in equation (A. 123) and limited between 0,0625 and 0,5.

## A.2.2 Example configuration

Table A.4 shows some examples applicable for VoIP scenarios using 64 kbit/s gross rate.

**Table A.4: Configuration of secondary and primary frames**

| Label | Primary frame | | Secondary frame | |
|---|---|---|---|---|
| | bit rate | Bandwidth (Hz) | bit rate | Bandwidth (Hz) |
| NB VoIP | 32 kbit/s | 4 000 | 32 kbit/s | 4 000 |
| WB VoIP | 32 kbit/s | 8 000 | 32 kbit/s | 8 000 |
| SWB VoIP | 48 kbit/s | 16 000 | 16 kbit/s | 4 000 |
| FB VoIP | 48 kbit/s | 20 000 | 16 kbit/s | 4 000 |

A script-based simulation framework `tools/lc3plus_redundancy_simulator.pl` can be found in archive ts_103634v010701p0.zip which accompanies the present document. The simulation assembles primary and secondary frames into a new bit stream based on a given error pattern. Secondary frames are labelled with BFI = 3 in the G192 file format. An example call is given in `tools/lc3plus_redundancy_example.sh`.

# Annex B (normative): RTP payload format for the LC3plus codec

## B.1 Introduction

This annex specifies the payload format for packetization of the Low Complexity Communication Codec (LC3plus) coded speech and/or audio signals into the Real-time Transport Protocol (RTP).

The RTP payload format is specified in clause B.2 and supports transmission of:

- different audio bandwidths and sampling frequencies;
- different frame durations;
- encoding at different bitrates;
- high-resolution encoding;
- multiple frames per payload;
- signalling for fast codec rate adaptation;
- single as well as multiple audio channels;
- application layer redundancy, including both codec redundancy and packetization redundancy.

SDP parameters are defined in clause B.3. Usage of the SDP parameters in in the offer-answer model is included in clause B.3.

The RTP payload format is intended to be used when transmitting LC3plus coded audio in IP/UDP/RTP networks. The payload format supports both single-channel operation as well as multi-channel operation as shown in Figures B.1 and B.2.

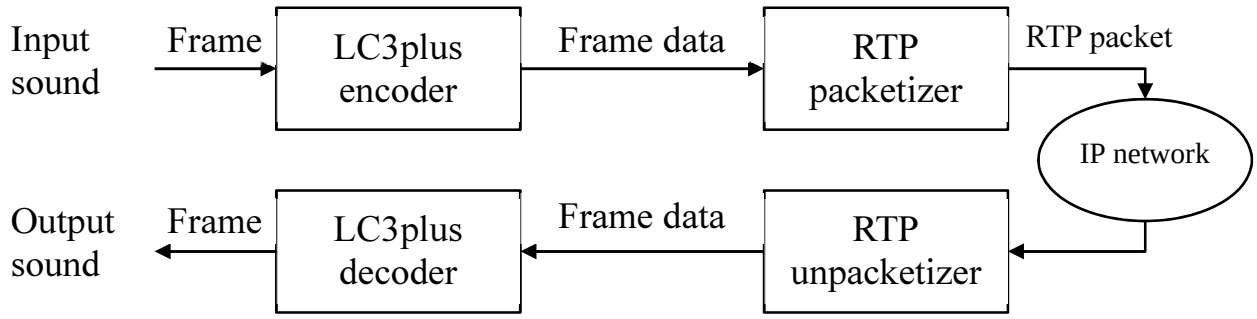

**Figure B.1: Single-channel operation**

For multi-channel operation, several independent instances of the LC3plus codec are used but the payload format supports packetizing frames from several codecs into the same RTP packet, as shown in Figure B.2.

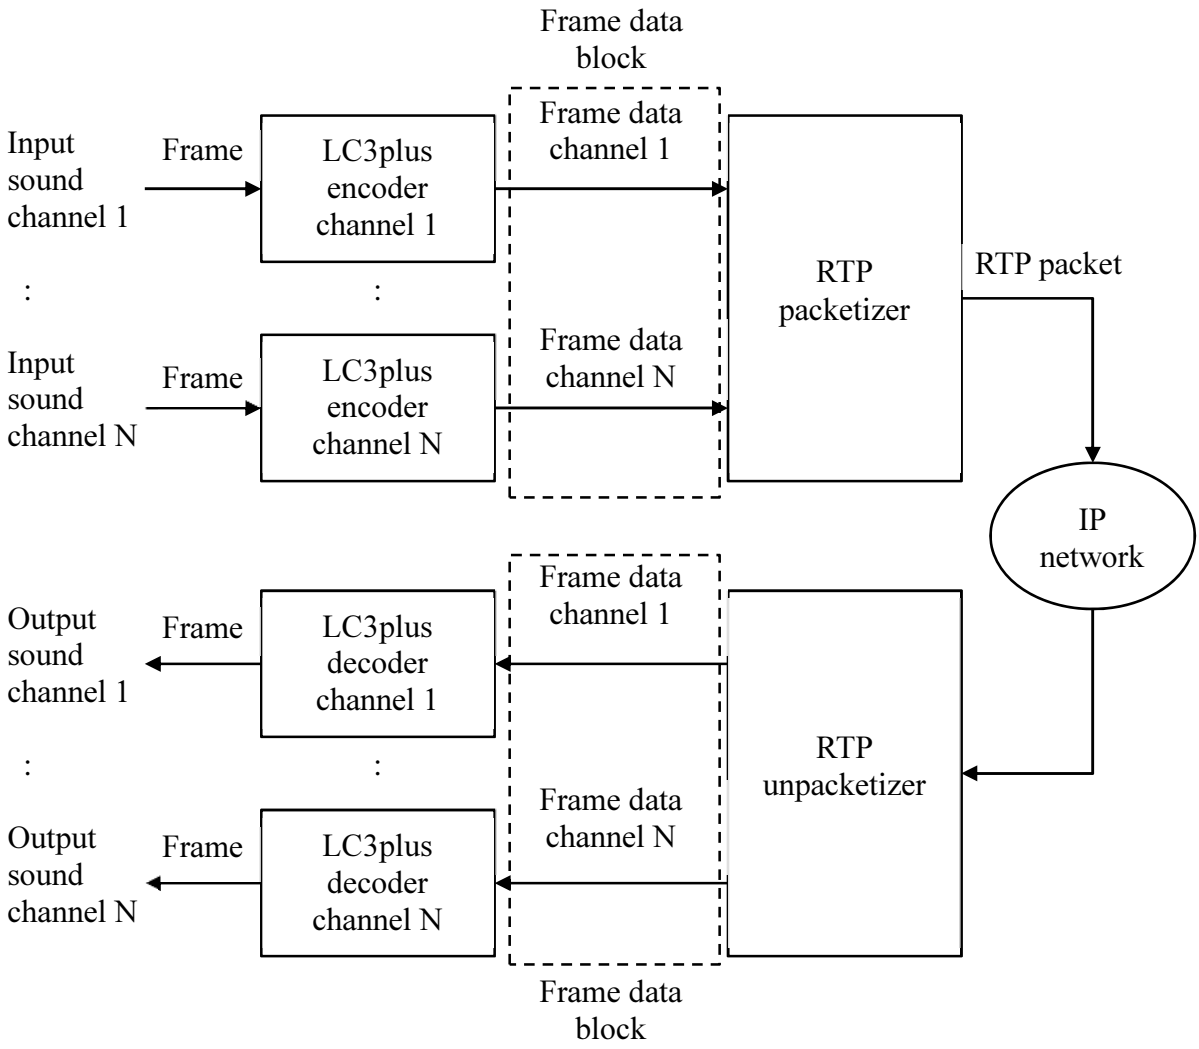

**Figure B.2: Multi-channel operation**

# B.2 LC3plus RTP payload format

## B.2.1 Byte order

The byte order used in the present document is the network byte order, i.e. the most significant byte (octet) first. The bit order is the most significant bit first. This practice is presented in all figures as having the most significant bit located left-most on each line and indicated with the lowest number.

## B.2.2 RTP header usage

### B.2.2.1 General

The format of the RTP header is specified in IETF RFC 3550 [2]. This payload format uses the fields of the RTP header in a manner consistent with IETF RFC 3550 [2].

### B.2.2.2 Marker bit

When an RTP stream is used for transporting a single audio channel, the RTP header marker bit (M) shall be set to 1 if the first frame-block carried in the RTP packet contains a speech frame which is the first in a talkspurt. For all other RTP packets the marker bit shall be set to zero (M=0). This is the same usage as described in IETF RFC 3551 [3].

When an RTP stream is used for transporting multiple channels, the RTP header marker bit shall be set to 1 if any of the channels contains a speech frame that is the first in the talkspurt and when all channels were inactive (in DTX) for the preceding frame period.

### B.2.2.3 Sequence number

The RTP Sequence Number is incremented by 1 for each transmitted packet, as described in IETF RFC 3550 [2].

### B.2.2.4 Time stamp

The RTP clock rate for the LC3plus codec is defined based on the audio bandwidth that is allowed for the payload type. The RTP clock rate may therefore be different for different LC3plus payload types and is chosen as shown below:

- Payload types supporting NB, WB, SSWB, SWB, FB, FBHR or UBHR (but not FBCD) use an RTP clock rate of 96 000 (Hz). The Time Stamp Increment (TSI) between consecutive frame data blocks then becomes:
  - For 1,25 ms frame duration: 120
  - For 2,5 ms frame duration: 240
  - For 5 ms frame duration: 480
  - For 10 ms frame duration: 960
- Payload types supporting FBCD (but none of the other audio bandwidths) use an RTP clock rate of 44 100 (Hz). The TSI between consecutive frame data blocks then becomes:
  - For 1,36 ms frame duration: 60
  - For 2,72 ms frame duration: 120
  - For 5,44 ms frame duration: 240
  - For 10,88 ms frame duration: 480

Sessions may consist of several payload types of any combination of NB, WB, SSWB, SWB, FBCD, FB, FBHR and UBHR. However, for each RTP payload type, only one of the audio bandwidths and therefore only one of the RTP clock rates can be used.

The RTP payload may contain multiple frame blocks of coded speech, comfort noise parameters (SID frames), bad frame indicator (Speech_bad) or NO_DATA frames in any combination. Within one RTP payload type, the frame duration shall be constant. The RTP Time Stamp corresponds to the sampling time of the first sample encoded by the first frame block in the packet, i.e. the oldest sample of the oldest frame.

The RTP Time Stamp may increment with any integer multiples of the Time Stamp increments indicated above, including 0 and even negative integers, depending on e.g. DTX usage, frame aggregation, application layer redundancy and redundancy offset.

## B.2.3 Packetization Considerations

A receiver shall be prepared to receive frame data multiple times, including both exact duplicates and encoded with different number of octets. If multiple versions of the same speech frame are received, the frame encoded with the largest number of octets should be used by the speech decoder. A frame shall not be encoded as speech in one packet and SID in another packet.

The payload length is always an integer number of octets. If additional padding is required to bring the payload length to a larger multiple of octets, then the P bit in the RTP in the header may be set and padding appended as specified in IETF RFC 3550 [2].

## B.2.4 Payload Structure

The payload format structure for the LC3plus codec is shown in Figure B.3.

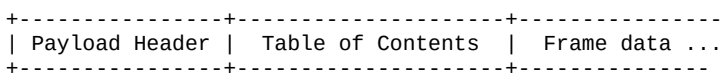

**Figure B.3: Payload format structure**

The Payload Header (PH) is variable size, 1, 2 or 3 octets, and contains the Frame Data Length Request (FDLR) as described in clause B.2.5.

The Table of Contents (ToC) includes one Frame Type Description (FTD) for each frame data included in the payload as described in clause B.2.4. The length of the ToC therefore depends on the number of frames encapsulated in the packet.

The audio data frame includes an integer number of octets, which may be different for different frames. The Frame Type Description describes the content of the corresponding audio data frame. The size (number of octets) of each frame data is derived from the FTD. The size of the frame data may be 0, which is the case for Speech_bad and NO_DATA frames, see clauses B.2.8 and B.2.9, respectively.

## B.2.5 Payload header, frame data length request

The payload header includes the Frame Data Length Request (FDLR) field, as described in Figure B.4.

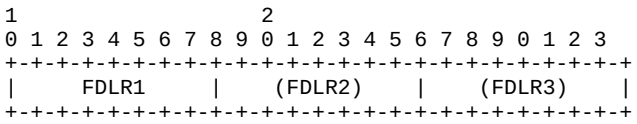

**Figure B.4: FDLR**

FDLR (8, 16 or 24 bits):
Indicates the frame data length that is requested by the media receiver. The FDLR is sent from the media receiver back to the media sender. The FDLR is encoded with 1, 2 or 3 octets as shown in Table B.1. The FDLR is represented with 1 octet (FDLR1) for values up to 254 and can be extended to 2 octets (FDLR1 and FDLR2) for values up to 509 and to 3 octets (FDLR1, FDLR2 and FDLR3) for values up to 765, see Table B.1. FDLR=0 is used to indicate NO_REQ; the media receiver is not allowed to request Speech_bad (FDLR=1) or SID (FDLR=2).

**Table B.1: FDLR encoding**

| FDLR index (decimal) | FDLR1 (binary) | FDLR2 (binary) | FDLR3 (binary) | Requested encoding size (#octets) |
|---|---|---|---|---|
| 0 | 0000 0000 | Not used | Not used | NO_REQ |
| 1 | 0000 0001 | Not used | Not used | Not allowed in FDLR |
| 2 | 0000 0010 | Not used | Not used | Not allowed in FDLR |
| 3 to 19 | 0000 0011 to 0001 0011 | Not used | Not used | Reserved |
| 20 to 254 | 0001 0100 to 1111 1110 | Not used | Not used | 20 to 254 |
| 255 to 509 | 1111 1111 | 0000 0000 to 1111 1110 | Not used | 254 to 509 |
| 510 to 765 | 1111 1111 | 1111 1111 | 0000 0000 to 1111 1111 | 765 |

The FDLR is used for adaptation purposes for bi-directional streams and indicates the FDL the media receiver wants to receive. In cases where the media sender is not sending any media packets but needs to send a FDLR, it is possible to generate an "empty" payload including only NO_DATA frame(s) to allow for sending the FDLR.

The FDLR indicates the maximum FDL the receiver wants to receive. The encoder may however use a lower FDL, if allowed by the session setup configuration.

A FDLR containing NO_REQ indicates that the media receiver has not included any Frame Data Length Request in the current payload. However, adaptation requests may also be sent with other means, e.g. using RTCP. Therefore, when a media sender receives a NO_REQ then this is ignored but other adaptation requests may be followed. If no previous FDLR has been received and if no other adaptation request using other means have been received, then the sender may use any of the FDLs allowed by the session setup and should use the highest FDL. If a previous FDLR other than NO_REQ has been received, then the previous FDLR is still valid. A FDLR is valid until it is updated by a later valid received FDLR other than NO_REQ.

When a media receiver sends a FDLR then the FDLR shall be:

- either an FDL allowed for the session; or
- NO_REQ.

An entity receiving a FDLR shall verify that the requested size is allowed by the session setup configuration. An entity receiving a FDLR requesting an FDL that is not allowed for the session shall ignore the FDLR.

The RTP payload shall always include exactly one payload header.

## B.2.6 Table of Contents

The Table of Contents (ToC) consists of one Frame Type Description (FTD) for each frame included in the RTP payload. Each FTD is 2, 3 or 4 octets long depending on the length of the Frame Data Length (FDL) field. The FTD describes the encoding of the corresponding audio frame. As shown in Figure B.5, all FTDs for all frames are encapsulated first in the RTP payload and the frame data for all frames are encapsulated after the last FTD. The FTDs are listed in the same order as the frame data in the RTP payload with the oldest frame included first and then further frame data are encapsulated in consecutive order. The structure of the ToC is shown in Figure B.5.

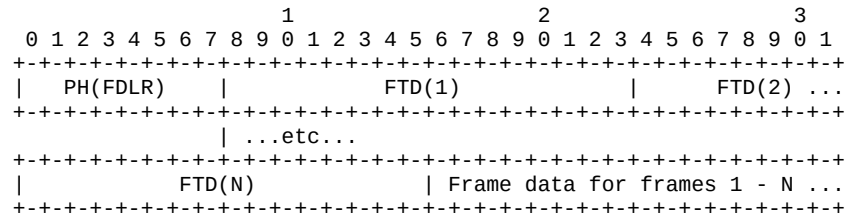

**Figure B.5: Example of payload including first the PH (1 octet FDLR), then the ToCs for N frames and then the frame data for N frames**

The content of the FTD is shown in Figure B.6.

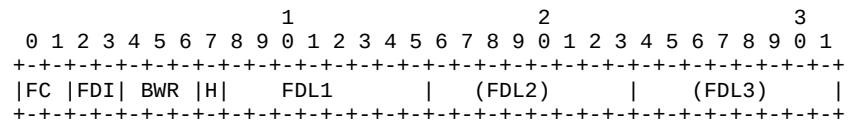

**Figure B.6: FTD content**

- FC (2 bits):
  - Frame and Channel (FC) indicator for subsequent frame data (if available). The meaning of the FC indicator is shown in Table B.2. The FC value defines the media time stamp (in integer increments of TSI) and the channel counter (CC, starting from 1 for the first channel) for the subsequent FTD (if available).

**Table B.2: FC encoding**

| FC | Description | TS next entry | CC next entry |
|---|---|---|---|
| 00 | Last FDL in ToC, no FDL follows the current FDL | N/A | N/A |
| 01 | The next FDL is for the next channel for the same media time | +=0 | +=1 |
| 10 | The next FDL is for first channel for next media time, channel counter is reset | +=TSI | =1 |
| 11 | Reserved | N/A | N/A |

- FDI (2 bits):
  - Frame Duration Index, with encoding as shown in Table B.3. The FDI shall be static for a given payload type during the session. The FDI also dictates the TSI, needed for deriving the media time in case of more than one frame in the payload.

**Table B.3: FDI encoding**

| FDI value (decimal) | FDI value (binary) | TSI (decimal) NB, WB, SSWB, SWB, FB, FBHR, UBHR | Frame duration NB, WB, SSWB, SWB, FB, FBHR, UBHR [ms] | TSI (decimal) FBCD | Frame duration FBCD [ms] |
|---|---|---|---|---|---|
| 0 | 00 | 240 | 2,5 | 120 | ca 2,72 |
| 1 | 01 | 480 | 5 | 240 | ca 5,44 |
| 2 | 10 | 960 | 10 | 480 | ca 10,88 |
| 3 | 11 | N/A | Reserved | N/A | Reserved |

- BWR (3 bits):
  -
    Bandwidth and resolution combination used by the codec is jointly encoded into a BandWidth and Resolution (BWR) index. The BWR index is encoded as shown in Table B.4. The BWR encoding is defined in Table B.4. The BWR index shall be static for a given payload type during the session.

**Table B.4: BWR encoding**

| BWR value (decimal) | BWR value (binary) | Bandwidth and Resolution |
|---|---|---|
| 0 | 000 | NB |
| 1 | 001 | WB |
| 2 | 010 | SSWB |
| 3 | 011 | SWB |
| 4 | 100 | FBCD |
| 5 | 101 | FB |
| 6 | 110 | FBHR |
| 7 | 111 | UBHR |

- H (1 bit):
  - Indicates whether the corresponding frame is a normal frame (primary encoding) or a helper frame (secondary encoding). 0 indicates a primary frame, 1 indicates secondary (redundant) frame.
- FDL (8, 16 or 24 bits):
  - Frame Data Length, indicates the number of octets used for the frame data. The frame data length is encoded with 1, 2 or 3 octets as shown in Table B.5. The FDL is represented with 1 octet (FDL1) for values up to 254 and can be extended to 2 octets (FDL1 and FDL2) for values up to 509 and to 3 octets (FDL1, FDL2 and FDL3) for values up to 765, see Table B.5.

**Table B.5: FDL encoding**

| FDL index (decimal) | FDL1 (binary) | FDL2 (binary) | FDL3 (binary) | Indicated encoding size (#octets) |
|---|---|---|---|---|
| 0 | 0000 0000 | Not used | Not used | NO_REQ |
| 1 | 0000 0001 | Not used | Not used | Speech_bad |
| 2 | 0000 0010 | Not used | Not used | SID |
| 3 to 19 | 0000 0011 to 0001 0011 | Not used | Not used | Reserved |
| 20 to 254 | 0001 0100 to 1111 1110 | Not used | Not used | 20 to 254 |
| 255 to 509 | 1111 1111 | 0000 0000 to 1111 1110 | Not used | 254 to 509 |
| 510 to 765 | 1111 1111 | 1111 1111 | 0000 0000 to 1111 1111 | 765 |

## B.2.7 Forming the payload

The RTP payload is formed by packing:

- first the payload header (FDLR); then
- all the FTDs for all the frames included in the payload; and
- then the audio data frames;

as shown in Figure B.7.

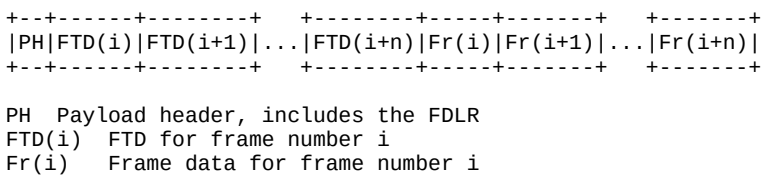

**Figure B.7: Payload including several FTDs and several frames**

Since all these elements are octet aligned then the created payload will also be octet aligned and no further padding should normally be needed.

If additional padding is needed, this is included at the end of the payload as described in IETF RFC 3550 [2].

The frame data bits are included in the payload in the same order as they are delivered from the encoder.

When several speech frames are included in the RTP payload, the ToC will include several FTDs, one for each frame data included in the RTP payload.

The FTDs in the ToC are included in the following order:

1) First the FTD for the first channel of the first FDB (oldest frame).
2) Then the FTDs for the remaining channels for the first FDB in increasing CC order.
3) Then the FTD for the first channel of the second FDB.
4) Then the FTDs for the remaining channels for the second FDB.
5) Etc. to the last FDB.

The FDBs are then appended after the ToC in the same order as the FTDs in the ToC.

## B.2.8 Speech_bad frame data

The receiver should verify that the received frame data is valid and error free. Such verification should also be done by Media Gateways.

If it is detected that the frame data is not valid, e.g. because of bit errors, then the frame data may be dropped and may be replaced by Speech_bad frame data. This is an explicit signalling to the media receiver that the frame data has been dropped. Knowing that a frame has been dropped can be beneficial for the media receiver because it then does not need to wait for the packet to be received. As a comparison, when a packet is lost in the transmission, then the jitter buffer would not know if or when the packet will be received until it decides to declare the packet as a late loss.

When Speech_bad frame data is received then the decoder normally activates the packet loss concealment for that frame. However, when redundancy transmission is used, the decoder should, whenever possible, use the redundant frame data received in other packets for the decoding instead of performing packet loss concealment.

An RTP packet may contain several Speech_bad frame data, one for each frame data that was found to be invalid.

## B.2.9 NO_DATA frames data

In some cases, there is a need for including an "empty" frame in the payload, for example when sending redundant data with offset. This is done by inserting a NO_DATA frame data in the place where an encoded frame data would normally be inserted. The NO_DATA frame data is not necessarily generated by the media sender but may also be inserted by an RTP packetizer in for example a Media Gateway (MGw). NO_DATA frame data can normally be ignored by the receiver but sometimes the decoder needs to do packet loss concealment for such frames, similar to frame losses, or decoder may need to generate comfort noise for such frames.

An RTP packet may contain several NO_DATA frame data, one for each frame where no actual frame data has been included.

## B.2.10 Example of NO_DATA or Speech_bad in payload

When the FTD indicates NO_DATA or Speech_bad then the corresponding frame data contains 0 byte. This means that two octets are included in the ToC for each NO_DATA and Speech_bad frame even if there are no corresponding actual frames among the list of frames. This is needed to be able to correctly determine the timing of any frames included in the payload after the NO_DATA or Speech_bad frame.

An example of this case is shown below where three frames are included in the payload, as shown by the three FTDs, but the second frame is a NO_DATA frame.

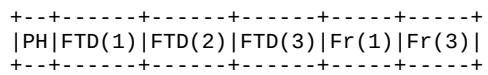

**Figure B.8: Payload including 3 frames where the 2nd frame is a NO_DATA frame**

| | |
|---|---|
| PH | Payload header, includes the FDLR |
| FTD(1) | FTD for frame 1 |
| FTD(2) | The FTD for the NO_DATA frame |
| FTD(3) | FTD for frame 3 |
| Fr(1) | Frame data for frame number 1 |
| Fr(3) | Frame data for frame number 3 |

The NO_DATA frame is, in this case, necessary because the media time for frame 1 is determined from the RTP Time Stamp, which is explicitly signalled in the RTP header, while the media time for frame 3 is implicitly determined from the media time for frame 1 by adding the frame periods for the preceding frames, i.e. 10 ms for frame 1 and another 10 ms for the NO_DATA frame (if 10 ms frames are used).

Inserting a Speech_bad frame is analogous to inserting a NO_DATA frame.

## B.2.11 Payload examples

### B.2.11.1 General

The following clauses give a few examples of how payloads may be generated.

### B.2.11.2 Single-Channel Payload Carrying a Single Frame Encoded with WB at 32 kbit/s

Figure B.9 shows a payload with:

- FDLR set to 0000 0000 to NO_REQ.
- Single channel (mono) with wideband audio.
- A single 10 ms audio frame is encoded with 32 kbit/s generating 40 octets (320 bits).
- The FTD describes:
  - The FC bits are set to 00, since there is no further frame in the payload.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 001, since wideband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.
  - The FDL field is set to 40 (0010 1000), since the size of the encoded frame is 40 octets.
- The frame data is represented with d(0) to d(319).

The payload size is 43 octets.

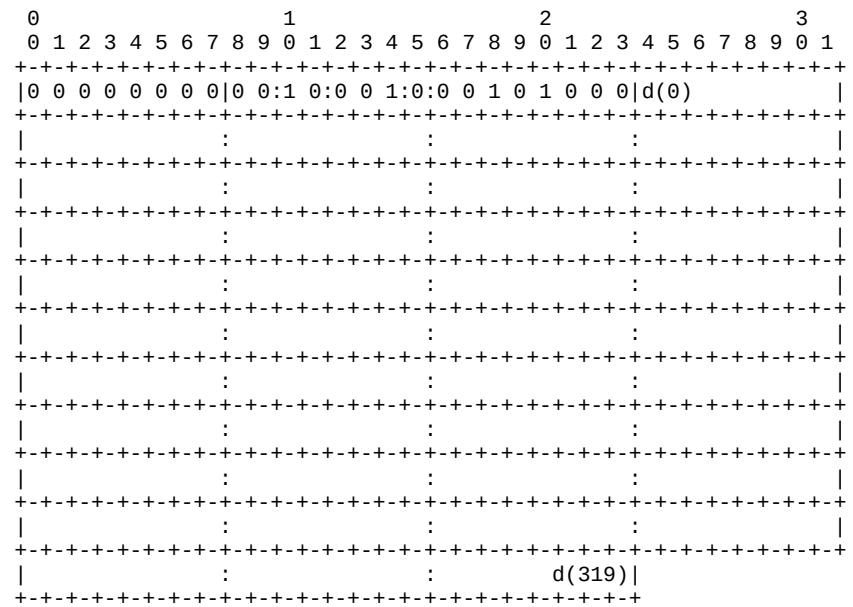

**Figure B.9: Payload including one 10 ms frame encoded at 32 kbit/s**

The RTP Time Stamp is set to represent the media time of the beginning of the 10 ms frame (first audio sample in the input frame).

### B.2.11.3 Single-Channel Payload Carrying a Single Frame Encoded with SWB at 64 kbit/s

Figure B.10 shows a payload with:

- FDLR set to 0000 0000 to NO_REQ.
- Single channel (mono) with superwideband audio.
- A single 10 ms audio frame is encoded with 64 kbit/s generating 80 octets (640 bits).
- The FTD describes:
  - The FC bits are set to 00, since there is no further frame in the payload.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 011, since superwideband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.
  - The FDL field is set to 80 (0101 0000), since the size of the encoded frame is 80 octets.
- The frame data is represented with d(0) to d(639).

The payload size is 83 octets.

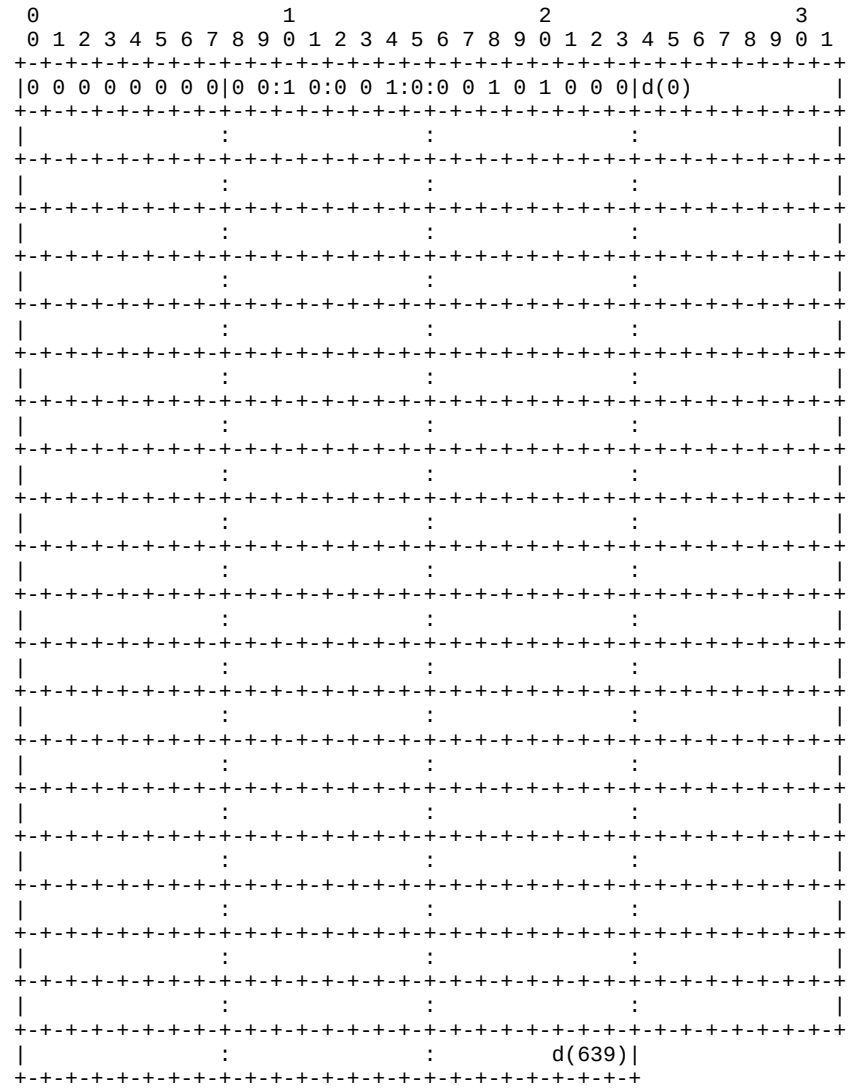

**Figure B.10: Payload including one 10 ms frame encoded at 64 kbit/s**

The RTP Time Stamp is set to represent the media time of the beginning of the 10 ms frame (first audio sample in the input frame).

## B.2.11.4 Single-Channel Payload Carrying Two Active Frames Encoded with WB at Different Bitrates

The diagram below shows a payload with:

- FDLR set to 0010 1000 to request 40 octets (320 kbit/s).
- 1 channel (mono) with wideband audio.
- Two 10 ms frames are encoded, the first encoded with 16 kbit/s generating 20 octets (160 bits), and the second frame encoded with 24 kbit/s generating 30 octets (240 bits).
- The FTD for the first frame describes:
  - The FC bits are set to 10, since another frame follow after the first frame and since there is one channel.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 001, since wideband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.

- The FDL field is set to 20 (0010 0100) since the size is 20 octets.

- The FTD for the second frame describes:
  - The FC bits are set to 00, since there is no further frame in the payload.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 001, since wideband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.
  - The FDL field is set to 30 (0001 1110) since the size is 30 octets.
- The 160 bits for the first frame are represented with d(1,0) to d(1,159).
- The 240 bits for the second frame are represented with d(2,0) to d(2,239).

The payload size is 1+2+2+20+30 = 55 octets.

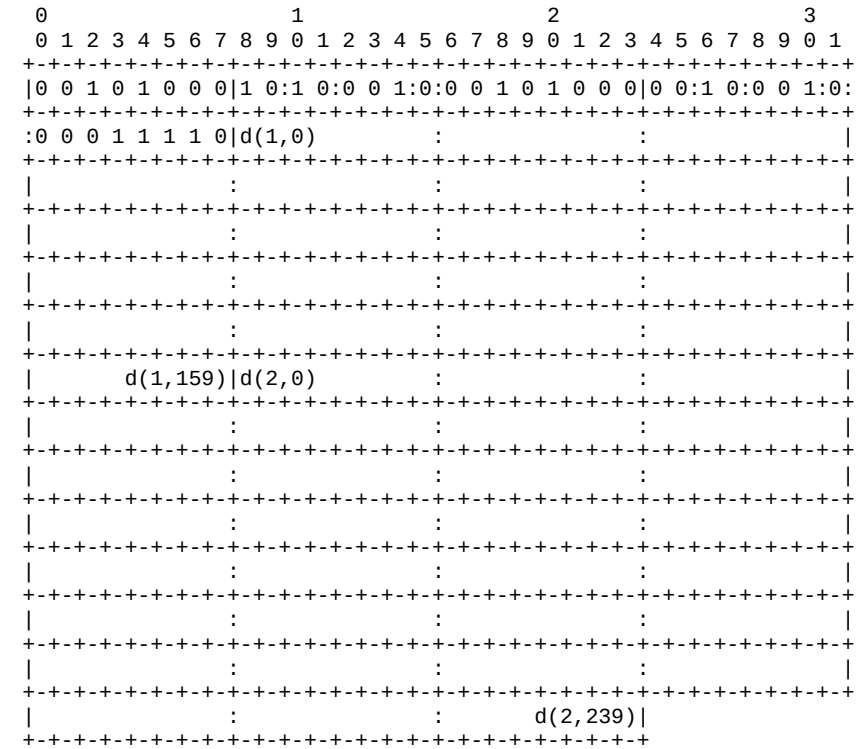

**Figure B.11: Payload including two 10 ms frames, the first encoded at 16 kbit/s and the second encoded at 24 kbit/s**

The RTP Time Stamp is set to represent the media time of the beginning of the first 10 ms frame (first sample in the first input frame). The receiver calculates the media time for the first frame from the RTP Time Stamp. To calculate the media time of the second frame, the receiver adds the frame duration of the preceding frame, in this case 10 ms.

## B.2.11.5 Multi-Channel Payload Carrying One Frame Block for Two Channels

The diagram below shows a payload with:

- FDLR set to request NO_REQ (0000 0000).
- 2 channels (stereo) with fullband audio.
- Two 10 ms frames are included, both are encoded with 96 kbit/s generating 120 octets (960 bits) per channel.

- The FTD for the first frame describes:
  - The FC bits are set to 01, since another frame for the next channel follows after the first frame and the media time is not to be incremented.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 101, since fullband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.
  - The FDL field is set to 120 (0111 1000) since the audio is encoded with 120 octets.
- The FTD for the second frame describes:
  - The FC bits are set to 00, since there is no further frame in the payload.
  - The FDI bits are set to 10, since the frame duration is 10 ms.
  - The BWR bits are set to 101, since fullband audio is transmitted.
  - The H bit is set to 0, since the frame is a primary frame.
  - The FDL field is set to 120 (0111 1000) since the audio is encoded with 120.
- The 960 bits of each frame are represented with d(1, 0) to d(1, 959) and d(2, 0) to d(2, 959), respectively.

The payload size is 1 + 2 + 2 + 120 + 120 = 245 octets.

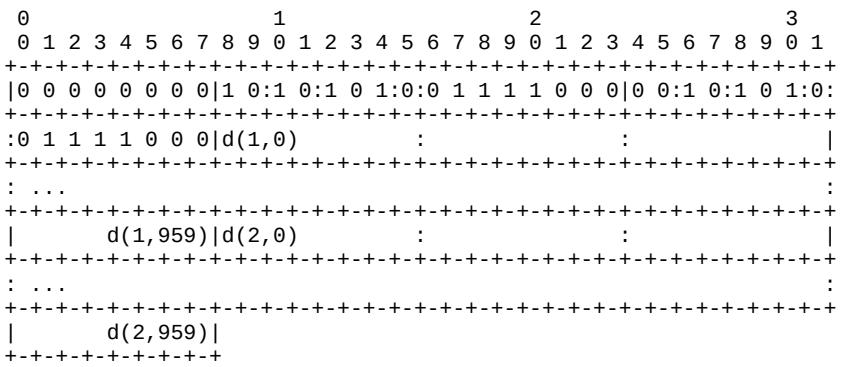

**Figure B.12: Payload including two 10 ms frames for 2 channels, both encoded at 96 kbit/s**

The RTP Time Stamp is used to determine the media time of the beginning of the frame period. The receiver then determine that the second frames is for the second channel and thus has the same media time as the preceding frame.

## B.2.12 Packetization

An implementation of this payload format shall support packetization of up to at least 20 ms (21,76 ms for FBCD), more specifically:

- 1 to 16 frames per packet for WB, SSWB, SWB, FB, FBHR and UBHR when 1,25 ms frame duration is used.
- 1 to 8 frames per packet for NB, WB, SSWB, SWB, FB, FBHR and UBHR when 2,5 ms frame duration is used.
- 1 to 8 frames per packet for FBCD when 2,72 ms frame duration is used.
- 1 to 4 frames per packet for NB, WB, SSWB, SWB, FB, FBHR and UBHR when 5 ms frame duration is used.
- 1 to 4 frames per packet for FBCD when 5,44 ms frame duration is used.

- 1 and 2 frames per packet for NB, WB, SSWB, SWB, FB, FBHR and UBHR when 10 ms frame duration is used.
- 1 and 2 frames per packet for FBCD when 10,88 ms frame duration is used.

This is because it is common to transmit about 50 packets per second for VoIP services. Furthermore, this also reduces the IP/UDP/RTP overhead that otherwise would become quite extensive when sending frequent small packets.

This does not mean that every packet will always include the maximum number of allowed frames, but also payloads with fewer frames shall be supported, enabling applications with lower latency at the expense of higher packet rate.

The packetization in a session is typically decided by the ptime value negotiated at session setup. However, this does not mean that the negotiated packetization is used for the entire session. The packetization may be both smaller and larger than the ptime value but is limited to the maxptime value (if negotiated).

# B.3 Payload format parameters

## B.3.1 General

This clause defines parameters of the LC3plus payload format.

This media type registration covers real-time transfer via RTP and non-real-time transfers via stored files. All media type parameters defined in this clause shall be supported. The receiver shall ignore any unspecified parameter.

The registrations are done following IETF RFC 4855 [5] and the media registration rules IETF RFC 3264 [1].

## B.3.2 LC3plus media type registration

| | |
|---|---|
| Media type name: | Audio. |
| Media subtype name: | LC3plus. |
| Required parameters: | Either bwr or both bwr-recv and bwr-send shall be included. |
| | Either fdi or both fdi-recv and fdi-send shall be included. |
| Optional parameters: | All remaining parameters specified below are optional. |

The parameters defined below apply to RTP transfer only.

ptime:
See IETF RFC 8866 [4].

maxptime:
See IETF RFC 8866 [4].

fdl:
Specifies the Frame Data Length (FDL) in integer number of octets, the set of FDLs or the FDL range allowed in the session for the send and the received directions.
The parameter can either have a single value (fdl1), a comma-separated list (fdl1, fdl2, …, fdlN) of values or a hyphen-separated pair of two values (fdl1-fdl2).
When a single value is included, then this FDL is the only allowed FDL.
When a comma-separated list is included, then all listed FDLs are allowed and FDLs that are not listed are not allowed.
When a hyphen-separated pair of values is used, then fdl1 defines the minimum FDL allowed and fdl2 defines the maximum FDL allowed. Any FDLs in-between these values are also allowed. The fdl1 value shall be smaller than fdl2 value.
If the fdl parameter is not present, and if neither fdl-recv nor fdl-send are present, then all integer sizes are allowed.

fdl-recv:

Specifies the FDL, the set of FDLs or the FDL range allowed in the session for the received direction, otherwise the same as the fdl parameter.
If both fdl and fdl-recv are included, then fdl-recv takes precedence over fdl.

fdl-send:

Specifies the FDL, the set of FDLs or the FDL range allowed in the session for the send direction, otherwise the same as the fdl parameter.
If both fdl and fdl-send are included, then fdl-send takes precedence over fdl.

bwr:

Specifies the audio BandWidth and Resolution (BWR) combination for the send and the receive direction.
During session setup, the parameter can either have a single value (bwr1) or comma-separated list (bwr1, bwr2, …, bwrN). When a comma-separated list is used, the bwr shall be listed with the lowest BWR value first and the remaining BWRs in increasing order, for example "bwr=nb,wb,sswb,swb".
It is not permitted to indicate fbcd in combination with any of the other BWRs. This is because FBCD uses a different RTP clock rate than the audio bandwidths. If it is desired to allow for FBCD and other audio bandwidths in a session, then a different RTP definition (different RTP payload type numbers) shall be used.

bwr-recv:

Specifies the audio bandwidth and resolution combinations for the receive direction, otherwise the same as the bwr parameter.
If both bwr and bwr-recv are included, the bwr-recv takes precedence over bwr.

bwr-send:

Specifies the audio bandwidth and resolution combinations allowed in the session for the send direction, otherwise the same as the bwr parameter.
If both bwr and bwr-send are included, the bwr-send takes precedence over bwr.

channels:

The number of audio channels per frame data block. See IETF RFC 3551 [3]. This parameter is included on the a=rtpmap line, for example "a=rtpmap: LC3plus/96000/1" where "/1" indicates the number of channels. If the channels parameter is not present, its default value is 1. If both ch-send and ch-recv are included (see below) with different numbers of channels for sending and receiving directions, channels is set to the larger of the two values.

ch-recv:

Specifies the number of audio channels to be used in the session for the receive direction.
The ch-recv parameter can be a single value, which is a strictly positive integer, i.e. 1 to any larger integer.
If ch-recv is not present, and if channels (see above) are not present, then ch-recv=1, mono, is used.

ch-send:

Specifies the number of audio channels to be used in the session for the send direction.
The ch-send parameter can be a single value, which is a strictly positive integer, i.e. 1 to any larger integer.
If ch-send is not present, and if channels (see above) are not present, then ch-send=1, mono, is used.

fdi:

Specifies the Frame Duration Index (FDI) in decimal form from Table B.3 allowed in the session for the send and the receive direction.
During session setup, the parameter can either have a single value (fdi1) or a comma-separated list (fdi1, fdi2, …, fdiN). When a comma-separated list is used, the FDIs shall be listed in increasing order.

fdi-recv:

Specifies the FDI in decimal form from Table B.3 allowed in the session for the receive direction, otherwise the same as the fdi parameter.
If both fdi and fdi-recv are included, then fdi-recv takes precedence over fdi.

fdi-send:

Specifies the FDI in decimal form from Table B.3 allowed in the session for the send direction, otherwise the same as the fdi parameter.
If both fdi and fdi-send are included, then fdi-send takes precedence over fdi.

max-red:

See IETF RFC 4867 [6].

rfdl:
: Specifies the redundant FDL in integer number of octets, where the redundancy is created by the LC3plus codec. The parameter can either be a single value ("rfdl=pr1"), a comma-separated list ("rfdl=rfdl1,rfdl2,…, rfdlN") or a range ("pred=rfdl1-rfdl2").
Including the rfdl parameter in the SDP means that codec redundancy is supported but is not required to be used.
Omitting the rfdl parameter in the SDP means that codec redundancy is not to be used.
This parameter does not control the packetization redundancy created by the LC3plus payload format.

rfdl-recv:
: Specifies the redundant FDL, the set of redundant FDLs or the redundant FDL range allowed in the session for receiving direction, otherwise the same as the rfdl parameter.
If both rfdl and rfdl-recv are included, then rfdl-recv takes precedence over rfdl.

rfdl-send:
: Specifies the redundant FDL, the set of redundant FDLs or the redundant FDL range allowed in the session for sending direction, otherwise the same as the rfdl parameter.
If both rfdl and rfdl-send are included, then rfdl-send takes precedence over rfdl.

### B.3.3 Mapping media type parameters into SDP

The information carried in the media type specification has a specific mapping to fields in the Session Description Protocol (SDP) IETF RFC 8866 [4], which is commonly used to describe RTP sessions. When SDP is used to specify sessions employing the LC3plus codec, the mapping is as follows:

- The media type ("audio") goes in SDP "m=" as the media name.
- The media subtype (payload format name) goes in SDP "a=rtpmap" as the encoding name. The RTP clock rate in "a=rtpmap" shall be set according to clause B.2.2.4 and the encoding parameters (number of channels) shall either be explicitly set to N or omitted, implying a default value of 1. The values of N that are allowed are specified in section 4.1 in IETF RFC 3551 [3].
- The parameters "ptime" and "maxptime" go in the SDP "a=ptime" and "a=maxptime" attributes, respectively.
- Any remaining parameters go in the SDP "a=fmtp" attribute by copying them directly from the media type parameter string as a semicolon-separated list of parameter=value pairs.

### B.3.4 Offer-answer model considerations

The following considerations apply when using SDP Offer-Answer procedures to negotiate the use of LC3plus payload in RTP:

fdl:
: If the SDP offer included a FDL range, it is permissible to include a FDL range, a comma-separated list of FDLs or a single FDL in the SDP answer.
If the SDP offer included a comma-separated list of FDLs, it is permissible to include a comma-separated list or a single FDL in the SDP answer but not a FDL range.
If the SDP offer includes a single FDL, the answerer shall either accept this or reject the payload type. The answerer is in this case not allowed to change the value.
The value(s) in the fdl in the SDP answer shall be identical to or a subset of the value(s) in the fdl in the SDP offer.

fdl-recv:
: The value(s) for fdl-send or fdl shall be identical to or a subset of fdl-recv for the payload type in the SDP offer.

fdl-send:
: The value(s) for fdl-recv or fdl shall be identical to or a subset of fdl-send for the payload type in the SDP offer.

bwr:

The offerer may indicate several BWR values in the SDP offer but the answerer shall select one BWR from the offered BWR values and include this in the SDP answer.
If the offerer wants to allow for switching between audio bandwidths and/or resolutions within a session, for example to allow for switching between NB, WB and SWB, then the SDP offer needs to include one RTP definition (one RTP payload type number) for each respective audio bandwidth and resolution combination.

bwr-recv:

When bwr-recv is offered for a payload type and the payload is accepted, the answerer shall select one of the indicated BWR values and include this in the bwr-send parameter in the SDP answer.

bwr-send:

When bwr-send is offered for a payload type and the payload is accepted, the answerer shall select one of the indicated BWR values and include this in the bwr-recv parameter in the SDP answer.

channels:

See <encoding parameters> of a=rtpmap attribute specified in IETF RFC 8866 [4] and clause B.3.2.

ch-recv:

When ch-recv is offered for a payload type and the payload type is accepted, the answerer shall include ch-send in the SDP answer, and the ch-send shall be identical to the ch-recv parameter for the payload type in the SDP offer.

ch-send:

When ch-send is offered for a payload type and the payload type is accepted, the answerer shall include ch-recv in the SDP answer, and the ch-recv shall be identical to the ch-send parameter for the payload type in the SDP offer.

fdi:

The offerer may indicate several FDI values in the SDP offer but the answerer shall select one FDI from the offered FDI values and include this in the SDP answer.
If the offerer wants to allow for switching between frame durations, for example to allow both 5 ms and 10 ms frame durations, then the SDP offer needs to include one RTP definition (one RTP payload type number) for each respective frame duration.

fdi-recv:

When fdi-recv is offered for a payload type and the payload is accepted, the answerer shall include fdi-send in the SDP answer, and shall select one of the indicated FDI values.

fdi-send:

When fdi-send is offered for a payload type and the payload is accepted, the answerer shall include fdi-recv in the SDP answer, and shall select one of the indicated FDI values.

rfdl:

If the SDP offer included a redundant FDL range, it is permissible to include a redundant FDL range, a comma-separated list of redundant FDLs, a single redundant FDL or reject the redundant FDL in the SDP answer.
If the SDP offer included a comma-separated list of redundant FDLs, it is permissible to include a comma-separated list, a single redundant FDL or reject the redundant FDL in the SDP answer but not a redundant FDL range.
If the SDP offer includes a single redundant FDL, the answerer shall either accept this or reject the redundant FDL.

rfdl-recv:

When rfdl-recv is offered for a payload type and the payload type is accepted, the answerer may include rfdl-send in the SDP answer, and the rfdl-send shall be identical to or a subset of rfdl-recv for the payload type in the SDP offer.

rfdl-send:

When rfdl-send is offered for a payload type and the payload type is accepted, the answerer may include rfdl-recv in the SDP answer, and the rfdl-recv shall be identical to or a subset of rfdl-send for the payload type in the SDP offer.

## B.3.5 SDP examples

### B.3.5.1 General

A number of SDP offer/answer examples are included below to describe different aspects of the session negotiation for several session variants.

In these examples, long a=fmtp lines are folded to meet the column width constraints of the present document; the backslash ("\") at the end of a line and the carriage return that follows it should be ignored.

### B.3.5.2 SDP negotiation for WB

This example shows the negotiation when offering LC3plus for wideband audio. Recommendations ITU-T G.722 [i.12] and G.726 [i.13] are also included to ensure fallback to legacy used codecs would be possible in case the answerer does not support the LC3plus codec.

The SDP offer includes: NB and WB; both 5 ms and 10 ms frame length; and an FDL range from 20 bytes to 40 bytes (16 kbit/s to 32 kbit/s). The recommended packetization (ptime) is set to 20 ms with a maximum packetization limit of 240 ms.

The answerer accepts to use LC3plus for wideband audio and accepts to use SWB, 10 ms frame length. However, instead of allowing an FDL range, the answerer limits the FDLs to four different sizes. The recommended packetization is set to 20 ms but the maximum packetization is limited to 80 ms.

**Table B.6: SDP example**

| **Example SDP offer** |
|---|
| m=audio 49152 RTP/AVP 96 97 98<br>a=rtpmap:96 G726-32/8000/1<br>a=rtpmap:97 G722/8000/1<br>a=rtpmap:98 LC3plus/96000/1<br>a=fmtp:98 bwr=nb,wb; fdl=20-40; fdi=1,2<br>a=ptime:20<br>a=maxptime:240 |
| **Example SDP answer** |
| m=audio 49154 RTP/AVP 98<br>a=rtpmap:98 LC3plus/96000/1<br>a=fmtp:98 bwr=wb; fdl=20,26,32,36; fdi=2<br>a=ptime:20<br>a=maxptime:80 |

### B.3.5.3 SDP negotiation for SWB

This example shows the negotiation when offering LC3plus for superwideband audio. Recommendations ITU-T G.722 [i.12] and G.726 [i.13] are also included to ensure fallback to legacy used codecs would be possible in case the answerer does not support the LC3plus codec.

The SDP offer includes: NB-SWB; both 5 ms and 10 ms frame length; FDL range from 20 bytes to 80 bytes (16 kbit/s to 64 kbit/s). The recommended packetization (ptime) is set to 20 ms with a maximum packetization limit of 240 ms.

The answerer accepts to use LC3plus for superwideband audio and accepts to use SWB, 10 ms frame length. However, instead of allowing an FDL range, the answerer limits the FDLs to four different sizes. The recommended packetization is set to 20 ms but the maximum packetization is limited to 80 ms.

**Table B.7: SDP example**

| Example SDP offer |
|---|
| m=audio 49152 RTP/AVP 96 97 98<br>a=rtpmap:96 G726-32/8000/1<br>a=rtpmap:97 G722/8000/1<br>a=rtpmap:98 LC3plus/96000/1<br>a=fmtp:98 bwr=nb,wb,swb; fdl=20-80; fdi=1,2<br>a=ptime:20<br>a=maxptime:240 |
| **Example SDP answer** |
| m=audio 49154 RTP/AVP 98<br>a=rtpmap:98 LC3plus/96000/1<br>a=fmtp:98 bwr=swb; fdl=20,40,60,80; fdi=2<br>a=ptime:20<br>a=maxptime:80 |

## B.4 IANA considerations

One media type (LC3plus/audio) has been updated, see clause B.3.

# Annex C (informative): An example FEC control unit

## C.1 Overview

The FEC control unit, as displayed in Figure A.1, is responsible for determining the optimal EP mode for the incoming stream when operated as receiver, and to select the EP mode for the outgoing stream when operated as transmitter. For bi-directional connections, both operations will be performed in each part. The determined optimal EP mode for the incoming stream is sent back to the other part as EP Mode Request (EPMR) and the EP mode for the outgoing stream is in turn set based on the EPMR received from the other part. In the following, the perspective of a bi-directional connection is taken.

EP mode selection from received EPMR is rather straight forward and described in clause C.4. Finding the right EPMR to be sent to the remote party, however, requires detailed analysis of the error statistics of the incoming stream. The suggested method's objective is to maximize the perceptual quality of the decoded audio signal, which is estimated using multiple frame error rate estimators. Note that this is different from minimizing the frame error rate itself. If e.g. the frame error rate was known to be 1 % in EP mode 1 and 0,5 % in EP mode 4, then an FER minimizing method would prefer EP mode 4 over EP mode 1. However, considering a 32 kbit/s WB speech connection, the speech deterioration caused by the lower net bitrate in EP mode 4 would be much higher than that one caused by 1 % FER in EP mode 1, where the missing frames are extrapolated by the very performant PLC.

An implementation of the algorithm is provided in archive ts_103634v010701p0.zip (folder fec_control_unit) which accompanies the present document.

## C.2 Parameters

### C.2.1 General

All frame based parameters are indexed with frame index $k$ starting with value 0.

### C.2.2 Setup Parameters

#### C.2.2.1 Minimal and maximal EP mode

Minimal and maximal EP Modes $m_0$ and $m_1$.

#### C.2.2.2 Perceptual quality table

A table $Q(r, m)$ indicating the expected perceptual quality at a frame error rate of $r$ in EP mode $m$, where $r \in \{0, 1, \ldots, r_{max}\}$ and $m \in \{m_0, m_0 + 1, \ldots m_1\}$. Such a table can, e.g. be generated by taking average MOS-LQO values over a relevant database with uniformly distributed frame losses. The table $Q(r, m)$ is subsequently extended to real values $r \geq 0$ via linear interpolation in the range $(0, r_{max})$ and by setting $Q(r, m)$ to $Q(r_{max}, m)$ for $r > r_{max}$. For a payload size of 40 bytes and NB, WB and SSWB content as well as for a payload size of 80 bytes and SWB content such tables are provided in the electronic attachment.

#### C.2.2.3 Initial FER reduction factors

FER reduction factors $red(k, m), m = m_0 + 1..m_1$ express the expected reduction of the frame error rate when switching from EP mode $m - 1$ to EP mode $m$. The initial values $red(-1, m)$ are specified at setup time. A suggested default setting is $red(k, m) = 0{,}5$ for all $m$.

## C.2.3 Input Parameters

### C.2.3.1 General

All input parameters are given per frame.

### C.2.3.2 EPOK flags

EPOK flags from incoming frame, denoted $epok(k,m)$. The value $epok(k,m)$ is derived from the value $epok_flags$ as defined in clause A.1.6.1 via:

$$epok(k,m) = bit_{m-1}(epok_flags). \tag{C.0}$$

$epok(k,m) = 1$ is then interpreted as 'frame $k$ would have been decodable in EP mode m', whereas $epok(k,m) = 0$ assumes the opposite.

### C.2.3.3 Other part's EPMR

Other part's decoded EPMR, i.e. the parameter $VKNI$ as defined in clause A.1.6, which is here denoted $epmr_{op}(k)$.

### C.2.3.4 Other part's detected EP mode

The value $n_{fec}$ from clause A.1.3.1.

## C.2.4 Output Parameters

### C.2.4.1 This part's EPMR

The parameter $epmr_{tp}$ to be transmitted back to the other part. Only present when this part is receiving audio.

### C.2.4.2 This part's EP mode

The parameter $m_{tp}$ to be used as EP mode for encoding the next outgoing frame. Only present when this part is sending audio.

## C.2.5 Derived Quantities

### C.2.5.1 Other part's assumed EP mode

The assumed EP mode of the other part is defined as:

$$m_{op}(k) := \begin{cases} n_{fec}, & n_{fec} > 0, \\ m_{op}(k-1), & else, \end{cases}, \tag{C.1}$$

with $m_{op}(-1) := m_0$.

### C.2.5.2 Bad frame indicator estimates

Bad frame indicator estimates $bfi(k,m)$ are calculated for every valid EP mode $m$ based on the received EPOK flags and last frame's FER reduction factors in the following way: if a non-zero EPOK flag exists (meaning the received frame was decodable), $bfi(k,m)$ is set to be $1 - epok(k,n)$. Otherwise, $bfi(k,m)$ is set to 1 for $m \leq m_{op}(k)$, assuming the EP mode equals the EP mode from the last frame and the current frame was lost in this EP mode. The potential frame loss for higher modes is then estimated by means of sampling. To this end, a random number $r$ is drawn from a uniform distribution on $[0,1]$ and the FER reduction rates from mode $m_{op}(k)$ to mode $m$ are calculated as:

$$r_m = \prod_{n=m_{op}(k)+1}^{m} red_stab(k-1,n), \tag{C.2}$$

with $red_stab(k-1,n)$as defined in clause C.2.5.6. For $m > m_{op}(k)$ the bad frame indicator estimate is then calculated as:

$$bfi(k,m) := \begin{cases} 1, & r_m > r, \\ 0, & else. \end{cases} \tag{C.3}$$

For negative frame indices $k$, $bfi(k,m)$ is defined to be 0.

### C.2.5.3 Frame error rate estimates

The frame error rate is estimated by calculating mean values of $bfi(k,m)$ over the most recent frames. This is done over three different lengths $N_S = 15, N_M = 225$ and $N_L = 3\ 375$ with update intervals $u_S = 1, u_M = 15$ and $u_L = 225$. The resulting values are denoted $FER_S(k,m)$, $FER_M(k,m)$, and $FER_L(k,m)$ and are computed as:

$$FER_X(k,m) := \begin{cases} \frac{1}{N_X}\sum_{l=k-N_X+1}^{k} bfi(l,m), & u_X \; divides \; k+1, \\ FER_X(k-1,m), & else, \end{cases} \tag{C.4}$$

where $FER_X(k,m)$ is defined to be 0 at negative frame indices $k$ and $X$ ranges over symbols $S$, $M$, and $L$.

### C.2.5.4 FER reduction factors

FER reduction factors are calculated on observed values of $bfi(k,m)$, i.e. for $m \leq m_{op}(k)$ and estimated by moving average. To be precise, FER reduction from mode $m-1$ to $m$ is observed, when:

$$m \leq m_{op}(k) \tag{C.5}$$

and

$$bfi(k,m-1) = 1 \tag{C.6}$$

For each mode $m$ let $N(k,m)$ denote the number of such frames and let $k_{m,i}$, $i = 0, \ldots, N(k,m)-1$ be an enumeration of all for which these conditions hold. Furthermore, $k_{m,i}$ is defined to be -1 for negative indices $i$. Then $red(k,n)$ is calculated as:

$$red(k,m) := \begin{cases} \frac{1}{N_{red}}\sum_{i=N(k,m)-100}^{N(k,m)-1} bfi\left(k_{m,i},m\right), & u_{red} \; divides \; N(k,m)+1, \\ red(k-1,m), & else, \end{cases} \tag{C.7}$$

with $N_{red} = 100$ and $u_{red} = 10$.

### C.2.5.5 Mean value estimator consistency

For a moving average mean value estimator $M_{(N,u)}(i)$ of length $N$ and with update interval $u$ dividing $N$ on a binary sequence $a_i$, a consistency value is calculated in the following way. Denote by $M_{(u,u)}(i)$ the corresponding mean value estimator of length $u$ and let $p = M_{N,u}(i)$. Then the estimator consistency at index $i$ is defined by:

$$cons(i) := \begin{cases} \dfrac{Np(1-p)}{\sum_{l=0}^{u-1}\left(up - uM_{u,u}(i-l)\right)^2} & 0 < p < 1, \\ 1, & else, \end{cases} \tag{C.8}$$

Consistency is calculated for FER estimates $FER_X(k,m)$ ($N = N_X, u = u_X, a_i = bfi(i,m)$) and denoted $cons_FER_X(k,m)$, and for FER reduction factors $red(k,m)$ ($N = N_{red}, u = u_{red}, a_i = bfi(k_{m,i}, m)$) and denoted $cons_red(k,m)$. Note that $cons_red(k,m)$ though indexed by $k$ actually only depends on the index $N(k,m)$, which may grow considerably slower than $k$.

### C.2.5.6 Stable reduction factors

Stable reduction factors $red_stab(k,m)$ are calculated as follows. First, a reference FER value $red_ref_FER(k,m)$ is assigned to every reduction factor estimate, which is defined to be $FER_L(k_{last}(m), m_0)$, where $k_{last}(m)$ is the last frame index at which $red(k,m)$ was updated. To be precise, $k_{last}(m)$ is the smallest value $\leq k$, such that:

$$N(k_{last}(m), \mathrm{m}) = u_{red}\left\lfloor \frac{N(k,m)+1}{u_{red}} \right\rfloor - 1, \tag{C.9}$$

Then, $red_stab(k,m)$ is set to $red(k,m)$ if the following two conditions are met:

1) $cons_red(k,m) > 0{,}2$

2) $FER_L(k,m_0)/1{,}5 < red_ref_FER(k,m) < FER_L(k,m_0) \cdot 1{,}5$

The first condition ensures that the reduction factor estimate is consistent and the second one that the long-term FER estimate did not change too much since the reduction estimate was last updated. If one of these conditions is not met, then the default value $red(-1,m)$ is chosen for $red_stab(k,m)$.

## C.3 EPMR selection

### C.3.1 FER estimator selection

For every valid EP mode one of three FER estimators labelled by the symbols S, M, and L is selected according to the flow chart depicted in Figure C.1, where the condition 'FER_X stable' is defined by $cons_{FER_X(k,m)} > 0{,}2$ and where the constants (a, b, c) are set to the values (30, 30, 4). This gives rise to a tuple of selected symbols $X(k,m)$ and with the ordering S < M < L the first FER estimator selection is set to $X_0(k) = \min_{m_0 \leq m \leq m_1} X(k,m)$. This first selection phase aims at selecting the longest stable estimator but takes sudden FER increases seen by shorter and more frequently updated estimators into account.

If a sudden increase in $FER_M$ is detected, the corresponding $FER_L$ estimator is treated as not stable until its value is updated. Similarly, if a sudden increase in $FER_S$ is detected, both the corresponding $FER_L$ and the corresponding $FER_M$ estimators are treated as not stable until their values are updated.

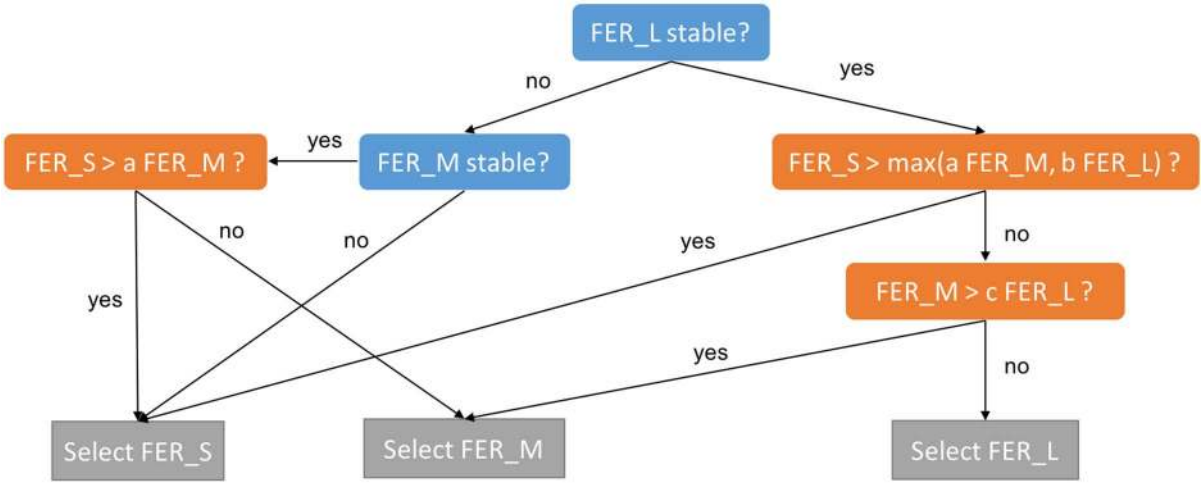

**Figure C.1: FER estimator selection**

## C.3.2 Optimal EPMR selection

For FER estimates $FER_{X_0(k)}(k,m)$, $FER_M(k,m)$ and $FER_L(k,m)$ the EP modes $m_X$ are determined which maximize the perceptual quality function $Q(FER_X(k,m),m)$. If no unique maximum exists, then $m_X$ is set to the smallest mode maximizing the perceptual quality function. The first selected EP mode is taken to be $m_{opt,0} = m_{X_0}$. Subsequently, two posterior rules are applied, which implement a hangover mechanism for downswitching the EP mode.

$$m_{opt,1} = \begin{cases} m_L - 1, & m_{opt,0} < 3 \; and \; m_{opt,0} < m_L - 1 \\ m_{opt,0}, & else \end{cases} \quad (C.10)$$

$$m_{opt,2} = \begin{cases} m_M, & m_{opt,1} < 2 \; and \; m_{opt,1} < m_M \\ m_{opt,1}, & else \end{cases} \quad (C.11)$$

If the connection is not bi-directional (in which case this part is the receiver) then $epmr_{tp}(k)$ is set to $m_{opt,2} - 1$. Otherwise, a third posterior rule is applied, based on the received values $epmr_{op}(k)$. To this end, let $L$ denote the largest integer such that $epmr_{op}(k-l) > 7$ for $0 \leq l < L$, i.e. the number of consecutive recent frames for which no high or medium confidence EPMR was received. Then this part's EPMR is set to:

$$epmr_{tp}(k) = \min\left(m_{opt,2} + \left\lfloor \frac{L}{10} \right\rfloor, m_1\right) - 1. \quad (C.12)$$

# C.4 EP mode selection

The first selected EP mode $m_{tp,0}(k)$ is set to $mod\left(epmr_{op}(k), 4\right) + 1$. If $epmr_{tp}(k) < 8$, i.e. the received EPMR is of high or medium confidence, the final EP mode $m_{tp}(k)$ is taken to be $m_{tp,0}(k)$. Otherwise, let $L$ be defined as in clause C.3.1. Then the final EP mode is selected as:

$$m_{tp} = \min\left(m_{tp,0} + \left\lfloor \frac{L}{10} \right\rfloor, m_1\right). \quad (C.13)$$

# Annex D (informative): Change history

| Date | Version | Information about changes |
|---|---|---|
| 2019-06-19 | 0.1.0 | First complete version for review and approval |
| 2019-06-26 | 0.1.1 | Added terms and abbreviations for RTP payload format in Annex B<br>Minor editorial updates |
| 2019-08-01 | 1.1.1 | Publication of DTS/DECT-00338 |
| 2020-02-19 | 1.1.2 | Freeze automatic clause numbering<br>Implemented CR on V1.1.1 (DECT(20)000011)<br>Software updated to V1.1.2; replaced kbps to kbit/s; integrated comments by DECT delegates; uploaded as early draft |
| 2020-04-15 | 1.1.3 | Implemented CR on V1.1.2 (DECT(20)000092r1)<br>Software updated to V1.1.3; integrated comments by DECT delegates; uploaded as early draft |
| 2020-07-29 | 1.1.4 | Editorial changes; software package identical as V1.1.3; ready as final draft |
| 2020-08-17 | 1.1.5 | Editorial changes to complete final draft |
| 2020-10-05 | 1.2.1 | Publication of RTS/DECT-00350 |
| 2021-04-07 | 1.2.2 | Implemented CR on V1.2.1 (DECT(21)000055); software updated to V1.2.2 |
| 2021-06-14 | 1.2.3 | Implemented CR on V1.2.2 (DECT(21)000139); software updated to V1.2.3 |
| 2021-07-09 | 1.2.4 | Implemented CR on V1.2.3 (DECT(21)000179); software updated to V1.2.4 |
| 2021-08-05 | 1.2.5 | Editorial changes to prepare final draft; cleaned up all CR defines in software and updated to V1.2.5 |
| 2021-10 | 1.3.1 | Publication of RTS/DECT-00369 |
| 2022-07-01 | 1.3.2 | Implemented CR on V1.3.1 (DECT(22)000129); software updated to V1.3.2 |
| 2022-11-30 | 1.3.3 | Implemented CR on V1.3.2 (DECT(22)000245); software updated to V1.3.3 |
| 2022-12-21 | 1.3.4 | Editorial changes for final draft; software updated to V1.3.4 (all defines accepted) |
| 2023-03 | 1.4.1 | Publication of RTS/DECT-00388 |
| 2023-09-25 | 1.4.2 | Implemented CR on V1.4.1 (DECT(23)000174, (23)000175, (23)000176); software updated to V1.4.2 |
| 2024-02-13 | 1.4.3 | Implemented CR on V1.4.2 (DECT(24)000043 corrected in DECT(24)000069); software updated to V1.4.3 |
| 2024-02-13 | 1.4.4 | Updated attached software according to (DECT(24)000043r1) |
| 2024-03-25 | 1.4.5 | Implemented CR on V1.4.4 (DECT(24)000066); software updated to V1.4.5 |
| 2024-04-15 | 1.4.6 | Editorial changes for final draft |
| 2024-05 | 1.5.1 | Publication of RTS/DECT-00399 |
| 2024-12-10 | 1.5.2 | Implementation of CR on V1.5.1 (DECT(24)000320r1) |
| 2025-03-10 | 1.5.3 | Implementation of CR on V1.5.2 (DECT(25)000056) |
| 2025-06-05 | 1.5.4 | Version skipped due to technical issues in ETSI portal |
| 2025-08-05 | 1.5.5 | Implementation of CR on V1.5.3 (DECT(25)000123), Software version still at 1.5.4 |
| 2025-10 | 1.6.1 | Publication of RTS/DECT-00417 |
| 2025-12-17 | 1.6.2 | Implementation of CR on V1.6.1 (DECT(25)000299), Software updated to V1.6.2 |
| 2026-04-30 | 1.6.3 | Implementation of CR on V1.6.2 (DECT(26)000129), Software updated to V1.6.3 |
| 2026-06-05 | 1.6.4 | Implementation of CR on V1.6.3 (DECT(26)000138), Software updated to V1.6.4 |
| 2026-07 | 1.7.1 | Publication of RTS/DECT-00437 |
